C

Cabot, Verne S., and Clay, Lyman B.: Unusually large ovarian cyst in an elderly woman (case report), 60
Cancer, A review of 174 cases of, with necropsies, 735
Carcinoma, bronchiogenic, Roentgen therapy of, 975
Carcinoma, Metastatic, of the heart, 860
Carcinoma of the papilla of Vater, 1174
Carcinoma of the right part of the colon, The surgical treatment of, 1197
Carcinoma, prostatic, Orchiectomy and hormones in, 403
Cardiac findings due to sternal depression, 1265
Cardiovascular roentgenology, A physiologic approach to, 1041
Case for diagnosis (thrombosis of left renal artery with acute infarction of left kidney, renal arteriosclerosis of right kidney, uremia, etc.), 766
Centenarian, The surgical history of a (case report), 767
Chest x-ray surveys, Community-wide, and the general practitioner, 625
Chest x-ray surveys, mass, Follow-up of abnormal pulmonary findings observed in, 1251
Choledochostomy tube removal, Criteria for, 315
Chordoma, 863
Chronic mastoiditis with cholesteatoma and stenosis of the external auditory meatus, 161
Chronic ulcers of the leg associated with congenital hemolytic jaundice (case report), 651
Chylothorax; pregnancy in an arrested case, 47
Circulation, A short commentary on the history of the, 264
Clay, Lyman B., and Cabot, Verne S.: Unusually large ovarian cyst in an elderly woman (case report), 60
Clinical use of folic acid, 1167
Colitis, ulcerative, Medical therapy in, 956
Collins, Arthur N.: Duodenal diverticulum, 268
Colon injuries, Exteriorization procedures for, 200
Colon, carcinoma of the right part of the, The surgical treatment of, 1197
Community-wide chest x-ray surveys and the general practitioner, 625
Congenital diaphragm of the duodenum (summary), 539; (complete paper), 745
Congenital dislocation and congenital subluxation of the hip, 889
Congenital urethral valve, 56
Constrictive fibrino-pleurisy, 1293
Cooney, Marion, and Kabler, Paul: Toxoplasmosis, 637
Coronary sclerosis, Further observations on the prognosis in angina pectoris due to, 162
Cor pulmonale, 514
Country medicine—past, present and future, 37
Coventry, Mark B.: Internal derangement of the knee, 42

74030

Creevy, C. D.: Ectopic kidney with hydronephrosis, 89
Criteria for choledochostomy tube removal, 315
Cruveilhier-Baumgarten syndrome, The, 506

Clinical-Pathological Conferences

Acute isolated myocarditis (Fiedler's myocarditis), 54
Carcinoma of the papilla of Vater, 1174
Chordoma, 863
Congenital urethral valve, 56
Cor pulmonale, 514
Epithelial neoplasms of the appendix, 176
Influenzal meningitis, 647
Kimmelstiel-Wilson syndrome, 280
Parathyroid adenoma, 760
Primary carcinoma of the pancreas, metastatic carcinomatous lymphangitis of the lungs, etc., 981
Rhabdomyosarcoma of the right interauricular septum, 282
Thrombosis of left renal artery, renal arteriosclerosis of right kidney, uremia, diabetes mellitus, 766

Communications

Ikeda, Kano, 1011
Ulrich, Henry L., 1094
Van Brussel, Martha: Our forgotten children, 210

D

Danielson, Earl A.: The Meeker County tuberculosis control project, 635
Deafness, a therapeutic problem, 642
Diverticula, Alimentary, 1284
Diverticulum, Duodenal, 268

Yeager, Charles L.: Polyneuritis, 166

"Hemostat, please . . . Thrombin."

Bleeding controlled, the operation proceeds.

THROMBIN TOPICAL, highly potent, rapidly acting hemostatic of biologic origin, is a distinct achievement for safer surgery— minor and major. Capillary hemorrhage may be arrested seconds after local application of THROMBIN TOPICAL.

Unending research in all the branches of medicine has led to the development of new Parke-Davis products, physiologically sound and clinically valuable. It has maintained as a continuing symbol of therapeutic significance the mark of Parke-Davis—MEDICAMENTA VERA.

THROMBIN TOPICAL is available in 5,000-unit ampoules, each packed with a 5 cc. ampoule of sterile, isotonic saline diluent.

PROTECT YOUR EARNING CAPACITY WITH LONG TERM NON-CANCELLABLE DISABILITY INSURANCE

The policy provides the following features:

NON-CANCELLABLE Guaranteed renewable to age of 60.

INCONTESTABLE Incontestable after 2 years, similar to your life insurance policies.

WAIVER OF PREMIUM After 90 days of total disability, premium payments are waived until such disability terminates.

NO HOUSE CONFINEMENT It is never necessary to be confined within the house to receive the indemnities provided.

BODILY INJURY Indemnity is paid on the basis of the result of the injury, not the manner in which it occurred.

NON-AGGREGATE The full policy limits payable for each new disability.

TOTAL DISABILITY Covers inability to engage in the insured's regular occupation, for 4 1/6 years, and thereafter for gainful occupation.

GRACE PERIOD In the payment of premiums, you are permitted a grace period of 31 days.

FULL MEDICAL EXAMINATION—required.

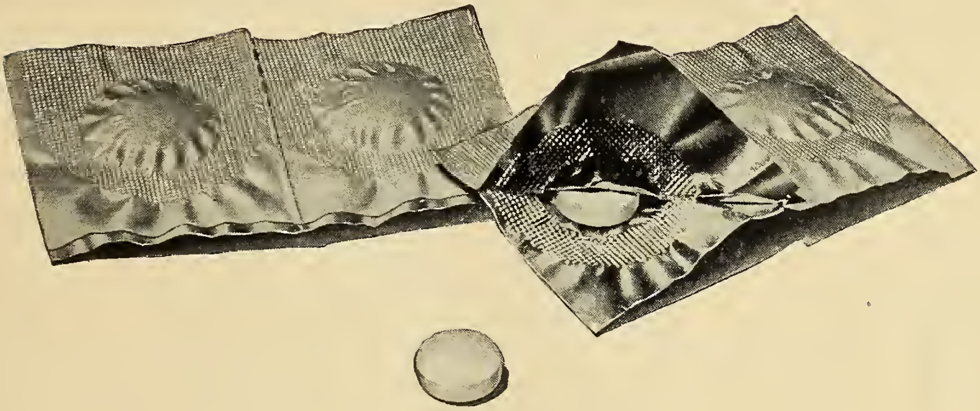
For the high dosage essential to the oral route

Squibb presents



A 50,000 UNIT TABLET OF PENICILLIN CALCIUM

"Provided enough is used . . . the oral route of administration of penicillin . . . is an effective way to treat infections" . . . requiring "five times as much, on the average . . ."[1] Parenteral medication should be used in the initial stages of acute infections, however, and Tablets Penicillin Calcium may be used effectively in the convalescent period following the remission of fever.

Highly potent, Tablets Penicillin Calcium Squibb simplify oral therapy by providing in a single tablet 50,000 units of the calcium salt of penicillin combined with 0.5 gm. trisodium citrate to enhance absorption as well as to attain "less irregular, higher and more prolonged blood levels."[2]

You can prescribe the precise number of tablets needed without fear of potency deterioration. *Each tablet* of Penicillin Calcium Squibb is *individually* and hermetically sealed in aluminum foil. Economical and convenient. Packages of 12 and 100. Refrigeration not necessary.

SPEED

WITH ACCURACY

BIRTCHER
ELECTROSURGICAL
UNITS

are precision-built for flawless service:

- ★ Cutting speed to satisfy the most critical requirements whether dry field or under water.
- ★ Control is easy and perfect, in cutting and hemostasis, separately or blended together.
- ★ Performance is unfailingly exact. Accurate calibration of control dials insures precise repetition of proved technics.
- ★ Dependability is assured.

These units meet the most rigorous demands and have proved outstanding in transurethral prostatic resection.

In the Early Recognition of Protein Deficiency

Unsupervised dietary curtailment and self-imposed food restrictions, not infrequently observed in elderly patients and in those desirous of preventing weight gain or losing weight, are apt to lead to multiple nutritional derangements. Not the least important among these, and often overlooked, is protein deficiency.

The early symptoms of chronic protein deficiency are vague and lack specificity. Thus they escape detection unless pointedly looked for. Easy fatigability, loss of weight, anorexia, malaise, and a slight pallor due to underlying secondary anemia constitute the most common complaints. A careful history of eating habits usually discloses the true significance of these symptoms.

Detection of the earliest objective sign of protein deficiency—negative nitrogen balance—requires hospitalization for several days, in order that nitrogen intake and excretion can be accurately determined.

Prolonged protein deficiency leads to hypoproteinemia, and is readily recognized by generalized edema and by a serum protein level below the normal 7 to 8 Gm. per 100 cc.

The most dependable and effective means of preventing and correcting protein deficiency is through proper organization of the diet. The recommended intake of 1 Gm. of protein per Kg. of body weight insures nitrogen balance in normal persons. For correction of frank protein deficiency, at least 2 Gm. per Kg. of body weight—and frequently considerably more—is required.

Among the protein foods of man, meat ranks high, not only because of the generous supply of protein it provides, but also because its protein is biologically complete, applicable for the satisfaction of every protein need.

The Seal of Acceptance denotes that the nutritional statements made in this advertisement are acceptable to the Council on Foods and Nutrition of the American Medical Association.

AMERICAN MEAT INSTITUTE

MAIN OFFICE, CHICAGO . . . MEMBERS THROUGHOUT THE UNITED STATES

Saved . . . by its foundation!

A strong foundation saved the Cathedral of Cologne in ground-shaking bombing assaults of World War II . . . and a strong nutritional foundation laid down in infancy will likewise help to protect health and strength in years to follow, against health-destroying assaults of disease. • BIOLAC furnishes among other essential nutrients the valuable proteins of milk, an outstanding source of all the indispensable amino acids . . . the prerequisite building blocks of strong tissues. • BIOLAC is bacteriologically safe...convenient...economical...readily available.

Biolac

ACCEPTED AMERICAN MEDICAL ASSN. Council on Foods and Nutrition

The foundation is the thing

Biolac is a liquid modified milk, prepared from whole and skim milk with added lactose, and fortified with thiamine, concentrate of vitamins A and D from cod liver oil, and iron citrate; only ascorbic acid supplementation is necessary. Evaporated, homogenized and sterilized. Biolac is available in 13 fl. oz. tins at all drug stores.

MODIFIED MILK FOR INFANTS
THE BORDEN COMPANY
NEW YORK, N. Y.

Quickly prepared . . . easily calculated: 1 fl. oz. Biolac to 1½ fl. oz. water per lb. of body weight.

Sinal drainage"... can be achieved by the introduction of nontoxic, volatile vasoconstrictors, such as ...amphetamine [Benzedrine]."

Russell, H.G.B., abstracted, Proc. Roy. Soc. Med. 36:401.

BENZEDRINE
INHALER

To relieve the discomfort of sinusitis

The vasoconstrictive vapor of Benzedrine Inhaler, N.N.R., diffuses evenly throughout the upper respiratory tract, opening sinal ostia and ducts which are frequently inaccessible to liquid vasoconstrictors. The sinuses drain. Headache, pressure pain, "stuffiness" and other unpleasant sinusitis symptoms are relieved.

Each Benzedrine Inhaler is packed with racemic amphetamine, S.K.F., 250 mg.; menthol, 12.5 mg.; and aromatics.

Smith, Kline & French Laboratories, **Philadelphia, Pa.**

Benzedrine Inhaler

a better means of nasal medication

Control of menopausal symptoms can be established promptly, in the majority of cases, by ORAL therapy alone. The extensive bibliography of "PREMARIN" offers convincing evidence that this highly potent, orally active, natural estrogen is a most effective therapeutic measure for treating the menopausal patient.

FLEXIBILITY

Pediatricians recognize the advantages of flexibility in prescribing infant feeding formulas, as the protein, fat, and carbohydrate requirement may vary with the individual baby. Formula preparation with CARTOSE* is simple, rapid, and accurate.

CARTOSE supplies carefully balanced proportions of nonfermentable dextrins in association with maltose and dextrose. Due to the time required for hydrolysis of the higher sugars, absorption is spaced. This lessens the likelihood of distress attributable to the presence of excessive amounts of readily fermentable sugars in the intestinal tract at one time.

When supplementation with vitamins of the B complex is indicated, KINNEY'S YEAST EXTRACT* is suggested for routine incorporation in the daily feeding. The full daily dose is simply added to the twenty-four-hour formula.

KINNEY'S YEAST EXTRACT is prepared from a specially cultured yeast and contains all the known factors of the B complex in natural, palatable form.

CARTOSE and KINNEY'S YEAST EXTRACT are offered for use under the guidance of physicians. They are available only at drugstores.

Molder of Minds . . . . .

Dietary Dub!

His diet is balanced, *yet he is a borderline vitamin deficiency case.* Like many others whose occupations are sedentary and who take little exercise otherwise, his caloric requirements and appetite are so small that he simply does not eat *enough* food to supply adequate quantities of the protective factors. As a result his case record has taken its place in his physician's file along with those of all of the other varieties of dietary delinquents: the ignorant and indifferent, patients "too busy" to eat properly, those on self-imposed and badly balanced reducing diets, excessive smokers, alcoholics, and food faddists, to name but a few. First thought in such cases is dietary reform, of course. But this is often more easily advised than accomplished. Because of this, an ever-growing number of physicians prescribe a vitamin supplement in every case of deficiency. If you're one of these physicians—or if you prescribe vitamins only rarely—consider the advantages of specifying an *Abbott* vitamin product: Quality—Certainty of potency—A line which includes a product for almost every vitamin need—And easy availability through pharmacies everywhere. Abbott Laboratories, North Chicago, Ill.

raison d'être

There are sound medical reasons for ESTINYL, an oral estrogen closely related to the primary follicular hormone, alpha-estradiol:

- it is the most potent oral estrogen known today,
- it controls hormonal deficiency symptoms rapidly,
- it is virtually free from side effects in therapeutic dosage,
- it induces the sense of well-being characteristic of the estrogenic hormone,
- it is economical—within the means of almost all patients.

ESTINYL

For menopausal patients one ESTINYL Tablet of 0.05 mg. daily is usually sufficient, but two or three tablets daily may be prescribed in the presence of severe symptoms.

ESTINYL (ethinyl estradiol) Tablets are best administered at bedtime.

Available in two strengths—0.05 (*five-hundredths*) mg. (pink) and 0.02 (*two-hundredths*) mg. (buff) tablets. Bottles of 100, 250 and 1,000.

Trade-Mark ESTINYL—Reg. U. S. Pat. Off.

Tonsillectomy ..... first in the series: "FACIAL EXPRESSIONS OF SICKNESS"

In the first stage of therapy, prophylaxis, the establishment of a moderate blood level of penicillin has been shown to be effective in reducing postoperative infections. This is particularly true in tonsillectomies. Here, a tablet of buffered penicillin every two hours, day and night, for 24 hours before the operation is a simple, yet effective means of avoiding secondary inflammation due to penicillin-sensitive organisms. For such prophylaxis, tablets of calcium penicillin, 50,000 units each, are available in bottles of 12.

43-ACRE REMEDY FOR GROWING PAINS

We think it's a healthy sign when a 51-year-old organization has growing pains. And our remedy is the purchase of a new 43-acre plant located in Milwaukee. It includes adequate provision for expanding production and accelerating engineering research and development of radiographic and therapeutic apparatus.

Important to you is the fact that the move from Chicago to Milwaukee will mean no interruption of the production schedules established to meet present delivery promises.

Our Chicago plant will continue to run at full capacity. The Milwaukee plant, already in operation, will gradually assume an increasing share of the manufacturing load.

Here, in this modern manufacturing facility, is concrete evidence of our plans to meet present and future demands of your profession. And your demands will be met without sacrificing the high quality and efficiency that have always characterized the products of this organization. Why do Tom, Dick and Harry need Vitamin D ?

Growing children require vitamin D mainly to prevent rickets. They also need vitamin D, though to a lesser degree, to insure optimal development of muscles and other soft tissues containing considerable amounts of phosphorus.

Milk is the logical menstruum for administering vitamin D to growing children, as well as to infants, pregnant women and lactating mothers. This suggests the use of Drisdol in Propylene Glycol, which diffuses uniformly in milk, fruit juices and other fluids.

Average daily dose for infants 2 drops, for children and adults 4 to 6 drops, in milk.

A good grip on life

With infant mortality at its highest during the first month of life, the fewer the burdens on the baby's endurance, the firmer will be his grip on life. And gastro-intestinal upset, colic and diarrhea can be heavy burdens for an infant.

'Dexin' has proved an excellent "first carbohydrate." Because of its high dextrin content, it (1) resists fermentation by the usual intestinal organisms; (2) tends to hold gas formation, distention and diarrhea to a minimum, and (3) promotes the formation of soft, flocculent, easily digested curds.

'Dexin' brand High Dextrin Carbohydrate is simply prepared in hot or cold milk and is readily adaptable to increasing formula needs. 'Dexin' *does* make a difference. 'Dexin' Reg. Trademark

NO. 7 in Schenley Laboratories' continuing summary of penicillin therapy.

EMPYEMA:
treatment with PENICILLIN SCHENLEY

Penicillin exhibits a marked ability to sterilize pleural effusions whenever the infecting organisms are penicillin-sensitive. It is most effective when administered in large doses during the incipient stages. Patients should be observed carefully for at least two weeks after discontinuance of penicillin therapy to avoid possible recurrence.[1]

In the management of empyema, it is especially appropriate to apply the maxim:

give enough-soon enough-long enough

[1] Poppe, J. K.: J.A.M.A. 129: 435 (Oct. 6) 1945.

PENICILLIN SCHENLEY. Treatment: Penicillin solution is injected directly into the pleural cavity after aspiration and after irrigation with sterile isotonic salt solution, if necessary. Penicillin should not be used for irrigation. The optimum dose for each injection is 50,000 to 200,000 units in a volume of solution less than the amount of fluid or pus aspirated. The frequency of injections depends on the extent, type, and severity of the infection, and the response to therapy. Treatment should be continued until after the fluid becomes sterile.

Surgical intervention is necessary if fibrin masses or loculation prevent adequate aspiration or if penicillin therapy is ineffective, as indicated by persistence of positive cultures after one week.

SYSTEMIC THERAPY. Systemic use of penicillin is indicated as a supplement to intrapleural therapy particularly where there exists an underlying active pulmonary infection or a bronchopleural fistula.

SCHENLEY LABORATORIES SERVICES:

1. Penicillin Paragraphs for January, dealing with empyema, has been mailed to all physicians.
2. A comprehensive penicillin dosage chart will be mailed to physicians on request.

ENDOCRINE THERAPY

EDWARD H. RYNEARSON, M.D.
Rochester, Minnesota

SINCE this paper was presented at the meeting of the Minnesota State Medical Association, there has appeared a booklet *Exhibit on Endocrine Products,* published under the auspices of the Council on Pharmacy and Chemistry of the American Medical Association. It was prepared by Drs. Austin Smith and Walton Van Winkle, Jr., and can be obtained by writing to the office at 535 North Dearborn Street, Chicago, Illinois. It supplies in one small booklet a much larger amount of information than was contained in my original remarks or will be written here.

What are some of the products of the endocrine glands which we physicians have found useful?

Thyroid

Desiccated thyroid is the most widely used (and misused) of all the hormones. It has several advantages: it is inexpensive, it is effective by mouth, and when properly used it is not toxic. It is so satisfactory that I know of no reason for the routine use of thyroxin, which is expensive and which belongs in the research laboratory. The most common use for thyroid is to elevate the basal metabolic rate. In cases of myxedema it constitutes complete replacement therapy. I have rarely seen a patient with myxedema who received more than 2 grains (0.13 gm.) daily as a maintenance dose, and in most instances there is a difference in response to variation of as little as ¼ grain (0.016 gm.). A patient may feel "low" with 1 grain (0.065 gm.), "too nervous" with 1½ grains (0.1 gm.), "just right" with 1¼ grains (0.08 gm.). This is quite a contrast to the patient who has a low basal metabolic rate without myxedema and who can take 3, 4 or 5 grains (0.2, 0.26 or 0.3 gm.) a day without any untoward symptoms. Having taken such an amount for some weeks, her basal metabolic rate is found to have risen dramatically from —18 per cent to —17 per cent! In these cases, the low rate is part of the general picture rather than the cause of the trouble, and justification for the use of thyroid depends on the patient's response rather than any changes in the basal metabolic rate. The use of thyroid in certain cases of menstrual disorders, sterility, and so forth, is also often empiric. Almost every obese patient receives thyroid at one time or another; very rarely is it of any help (unless "accompanied by a diet"). It is unfortunate that some obese patients are given prescriptions for excessive amounts of thyroid; one such patient was taking 32 grains (2.1 gm.) a day. She was reducing all right, and so were her chances for life. Thyroid is also very generously prescribed for "glandular imbalance," Mongolian idiocy, too much or too little hair, too thick or too thin fingernails and a host of other poorly defined conditions.

Parathyroid Hormone

I have never prescribed a single injection of parathyroid hormone for the treatment of acute or chronic parathyroid insufficiency. It is a very valuable hormone for research studies, but patients can be treated easily and inexpensively by

---

From the Division of Medicine, Mayo Clinic, Rochester, Minn. Read at the annual meeting of the Minnesota State Medical Association, Saint Paul, Minnesota, May 22, 1946.

the administration of calcium by mouth with vitamin D for absorption. The calcium, whether as lactate or as gluconate, should be dissolved in very hot water; unless a clear solution is administered it is very poorly absorbed. I am not prepared to say that there is no absorption from all the calcium powders and tablets which are administered, but I can say that I have never seen these help any patient who had true hypoparathyroidism. The amount of calcium required to control a patient's symptoms and elevate the serum calcium to normal varies in each case. Some patients require only 2 or 3 teaspoonfuls (8 or 12 gms.) of the powder daily; others, in cases of acute insufficiency, may require 16 or 20 teaspoonfuls (64 or 80 gms.). Vitamin D may be given as cod liver oil or one of the many preparations in concentrated forms. Calciferol and dihydrotachysterol (A.T. 10) are often of great value. One cubic centimeter of A.T. 10 taken daily by mouth every day or every other day will control the hypoparathyroidism of many patients. Parathyroid hormone can be used for such patients, but in addition to the expense there is always the risk of overtreatment, which produces the clinical picture of hyperparathyroidism.

Adrenal Cortex

Adrenal cortical extract is prepared by several firms. Its primary use is in the treatment of Addison's disease. The only synthetic fraction available for use is desoxycorticosterone acetate. Neither one satisfies most physicians. The extract is often too weak, and if sufficient amounts are given the cost is often prohibitive. The synthetic fraction is often unsatisfactory because its effect is incomplete, causing only a retention of salt and water. What we physicians hope for is either a more potent, less expensive, whole adrenal cortical extract or other synthetic fractions which will help with the other deficiencies present in Addison's disease, such as hypoglycemia. The synthetic fraction is usually prepared in oil and administered hypodermically. It can also be implanted as pellets. Preparations for oral or sublingual use are more wasteful than preparations for parenteral use. Some oral preparations, such as cortalex tablets, are too weak to be of any value in the treatment of Addison's disease; they are usually prescribed for "hypo-adrenia," whatever that might be.

Adrenal Medulla

Physicians are well acquainted with the indications and uses of epinephrine. Its vasoconstrictive effect has made it valuable in certain cardiovascular conditions, in asthma, in shock, and so forth.

Pancreas

Space does not permit a discussion of the various types of insulin and their use.

Estrogenic Substances

In the booklet mentioned at the beginning of this article, more than two pages are required simply for the listing of the commercial forms of estrogens. The booklet lists both the naturally occurring estrogens and all the varied synthetic fractions. It states:

> Estrogens may be administered by injection, by inunction with a suitable base, or by mouth. Estrone and estradiol lose considerable activity when taken orally. When estrone is administered in the form of its sulfate, it appears to retain a greater amount of its potency. Several estrogenic compounds have been prepared which lose relatively little potency when administered orally.
>
> Besides crystalline estrogens, preparations of highly purified but noncrystalline estrogens are available. These are usually extracted from the urine of pregnant women or pregnant mares; the estrogenic activity of such extracts is due almost entirely to estrone. The Council has coined the term Solution of Estrogens for such preparations.

There has been an enormous amount of clinical research with estrogenic substances. Claims for therapeutic results have been often exaggerated and confusing. Definite and consistently reliable results have been obtained in only a relatively small number of conditions. These include treatment of the symptoms of the menopause syndrome, natural or artificial, senile vaginitis, kraurosis vulvae, pruritus vulvae, gonorrheal vaginitis of children, hypogenitalism in the female, relief of engorgement of the breasts, interruption of excessive flowing in "functional bleeding," palliation of local discomforts from prostatic carcinoma and its metastases. All other indications should be considered unscientific or in the experimental stage of therapy.

Estrogens are carcinogenic when administered experimentally to animals which have an inherited sensitivity to the development of mammary carcinoma. Many clinicians believe that estrogens are therefore contraindicated in the treatment of women who have a familial or personal history of mammary or genital malignancy.

Progestins

The hormone of the corpus luteum is most important in normal female physiologic processes. It is essential for the inception of pregnancy and for its successful completion. My experience in female endocrinology is limited, and again I refer to this booklet:

> Commercial preparations of progesterone are either extracts of animal ovaries, or the pure compound prepared synthetically. At one time, there was considerable enthusiasm over the therapeutic use of such preparations in dysmenorrhea, menorrhagia and habitual abortion, but the volume of satisfactory evidence is too small to warrant dependence on progesterone for treatment of these conditions.

Androgens

Castration in the male produces the clinical picture recognized since the days of antiquity. For all these years, physicians have attempted to treat male gonadal deficiency in a variety of ways, including the widely publicized transplantation of "goat glands." In more recent years there have been available testosterone propionate (in oil, ointment or pellets) and methyl testosterone for oral or sublingual use or for administration in an ointment. These substances constitute adequate replacement therapy for those patients whose symptoms are caused by a lack of this hormone. Androgens also have other effects, such as a marked nitrogen-sparing effect, and encouraging reports have been published of their use in cases of inoperable carcinoma of the breast. There are conflicting opinions regarding their use in cases of gynecologic disorders and angina pectoris.

Without any facts to support the statement, I feel safe in saying that the largest amount of androgens is prescribed for nonspecific conditions. I refer particularly to such conditions as impotence and "male climacteric." Undoubtedly there are cases in which both conditions are real and respond to treatment. Again without facts to support me, I state my conviction that most men who are impotent are suffering from a psychic disturbance and that most men diagnosed as having "the male climacteric" are simply exhausted, frustrated, middle-aged men. Many of these men are helped by androgens, but in my opinion this is psychosomatic medicine in most instances. When controls were run, as they were at the University of Minnesota and at Johns Hopkins Hospital, for example, the men could not tell when they were getting the hormone and when they were receiving a placebo.

Anterior Pituitary

The anterior lobe of the pituitary is a most important gland. We are all familiar with pituitary dwarfism and the deficiency secondary to a chromophobe adenoma. We are equally familiar with the syndromes produced by overfunction, such as gigantism, acromegaly and Cushing's disease. We are all thrilled with the dramatic reports published by our friends in the laboratory wherein they recount their ability to isolate separate hormones or fractions which when injected into animals cause such startling changes.

But we are equally aware of our disappointment when we attempt to use commercially prepared anterior pituitary extracts in the treatment of patients. To my knowledge there has not been a single instance in which any patient suffering from postoperative pituitary insufficiency has been helped in any way by the injection of any anterior pituitary extract. This statement is almost equally applicable to the use of growth hormone in the treatment of dwarfism. Prolactin has been advised for the treatment of severe menstrual bleeding, but in general it may be said that the results of the injection of anterior pituitary hormones have been very disappointing. There is, of course, no evidence that any oral preparation is worth anything.

Posterior Pituitary

Surgeons and obstetricians have found important uses for pitressin and pitocin. We physicians are interested in the use of pitressin in the treatment of diabetes insipidus. It can be administered hypodermically in an aqueous solution or, for a prolonged effect, as pitressin tannate in oil. It can be administered in a jelly or on pledgets in the nose. The easiest, cheapest and usually most satisfactory method is to prescribe the posterior pituitary powder, which the patient introduces into the nose. The least wasteful method is to blow a small amount into the nose with an atomizer bulb and glass tube. Ordinarily a small amount of powder (easily measured on the tip of a small blade) insufflated in the morning and at night will control the symptoms.

Gonadotropic Substances

These are obtained (1) directly from the anterior pituitary gland, (2) from the serum of pregnant mares and (3) from the urine or placenta of pregnant women. They differ somewhat physiologically. For example, chorionic gonadotropin (2 and 3 in the preceding list) does not markedly stimulate the ovaries of monkeys or human beings. It may cause degenerative changes.

Chorionic gonadotropin has had wide use in the treatment of gynecologic disorders related to a real or supposed ovarian disturbance, particularly various abnormalities of menstruation, and in an attempt to overcome female infertility. It has been used alone and in various combinations with other hormones, particularly with the estrogens and progestins, in an effort to simulate the normal cyclic hormonal effects.

In both male and female patients chorionic gonadotropin has been used to stimulate gonadal development and often to produce generalized growth. Its primary use in male patients has been in the treatment of cryptorchidism. Astounding successes were listed in early reports but it became obvious that many of these patients did not have true cryptorchidism; with patience and warmth the testes would descend. There is now general agreement that this treatment will affect the descent of the testes of those boys whose testes will descend spontaneously when the delayed maturity is complete. There is no objection to hastening maturity and descent; many observers feel that there are good reasons for hastening them. These same observers feel that if descent does not occur after six to eight weeks of treatment, surgical intervention should follow, since the tissues are at that time most susceptible of repair. Other competent observers, however, are of the opinion that most of these testes will descend of their own accord and that the delayed descent is a manifestation only of delayed puberty. They recommend simply observation and patience. If testes do not descend when puberty is complete, then surgeons are fairly well in agreement that an effort should be made to bring the testes down surgically if both are undescended and that if one is undescended, it should either be brought down or removed. This conviction is based on the fact that testes cannot function normally unless they are in the scrotum and there is a higher incidence of carcinoma in intra-abdominal than in intrascrotal testes, although the incidence of carcinoma in either is rare.

Conclusions

Endocrinology continues to be a most fascinating study. Its reputation is enhanced by the brilliant advances from the laboratory and their careful application in the treatment of patients. Those who indiscriminately inject hormones into patients who have poorly defined conditions, and then report good results with never a control, are hurting rather than helping endocrinology. Physicians who regard these enthusiastic, unscientific papers with skepticism and criticism are labeled "nihilists." They would prefer to be called "realists," for they make an effort to determine what is real and to suspect that "10,000 patients suffering from crud; report of 100 per cent cures" may not represent a very scientific study.

FELLOWSHIPS FOR PHYSICIANS AND ENGINEERS

Announcement is made by Surgeon General Thomas Parran of the U. S. Public Health Service that applications for Fellowships in postgraduate public health training for physicians and engineers for the school year beginning in the fall of 1947 will be received at any time prior to May 1, 1947.

The Fellowships are made possible by a grant of $228,400 from the National Foundation for Infantile Paralysis through funds contributed to its March of Dimes. Fifty-three students were awarded Fellowships for the school year beginning in September, 1946.

The Fellowships provide an academic year's graduate training of approximately nine months in an accredited school of public health or an acceptable school of sanitary engineering followed by three months of field training, and are open to men and women, citizens of the United States, under forty-five years of age. Physician applicants must have completed at least a year's internship.

The specific purpose of the Fellowships is to aid in the recruitment of trained health officers, directors of special services, and engineers to help fill hundreds of vacancies existing in State and local health departments throughout the country. The Fellowships are intended for newcomers to the public health field, and are not open to employees of State and local health departments, for whom Federal grant-in-aid funds are already available to the States.

Applicants for Fellowships may secure further details by writing to the Surgeon General, U. S. Public Health Service, 19th and Constitution Avenue, N. W., Washington 25, D. C., Attention Public Health Training.

COUNTRY MEDICINE—PAST, PRESENT AND FUTURE

GEORGE E SHERWOOD, M.D.
Kimball, Minnesota

IT has been customary for the presiding officer of the Northern Minnesota Medical Association to contribute to the annual program by giving a presidential address. I wish to state at this time that I feel wholly inadequate for the occasion, as both my literary and oratorical ability are very limited. In fact, I feel a good deal like the man who, being of some prominence in his locality, had spent his summer vacation in making an extended European tour, and upon his return, as he left the palatial liner at New York, was approached by a representative of the *Atlantic Monthly* and asked if he would not contribute something to the next issue of that noted magazine. His answer was very brief and much to the point. He said that it would be impossible, as he had suffered from *mal de mer* ever since he boarded the ship and had been forced to contribute to the Atlantic daily.

It was some poet or philosopher, I believe, who said that brevity is the soul of wit. So I will take his advice, undoubtedly much to your gratification, and my part of the program will be very brief. We have such an unusual array of talent at the toastmaster's table that any remarks that I could make would be more or less superfluous and would add little to the eloquence of the occasion.

First, I wish to thank the members of this society for the honor of presiding over this organization for the past year. It has been my pleasure to have been affiliated with the Northern Minnesota Medical Association for a number of years and to have become quite well acquainted with a goodly share of its members. I assure you that its membership as a whole is composed of a high type of medical men, both as to character and professional attainments.

A few months ago there was held in Saint Paul the ninety-third annual meeting of the Minnesota State Medical Association. As the years have rolled by, the membership of that fine organization has become so large that it is almost unwieldy, and it has been found necessary to divide the meeting into different sections that meet simultaneously. Therefore, it is almost impossible for any ordinary member of the medical profession to contact and become acquainted with more than a small portion of its membership. Hence such sectional organizations as the Northern Minnesota Medical Association have a proper place in the economy of organized medicine. Having a much smaller membership and attendance at its meetings, it affords a better opportunity for its members to become acquainted with each other, and it should receive the encouragement and support of all medical men residing within its territory. This is especially true at this time, when the bureaucrats are doing their utmost to destroy the private practice of medicine and to regiment the medical profession under the guise of socialized medicine. If we do not stand together and put up a united front in opposition, they will very likely succeed.

It is now more than fifty years since your speaker located in a country town to practice his profession. Since that time there have been great changes in the conduct and administration of a country practice, as well as in the general practice of medicine and surgery, so that a physician who locates in the country today has little conception of the hardships and trials of a country doctor of half a century ago. Just as the airplane has destroyed the isolation of the world at large, so have the automobile, good roads, rural telephones and radio destroyed the isolation of country life. At the beginning of this century the roads as a rule were simply trails through the forests and over the prairies and for transportation we had to depend on horse-drawn vehicles. Hospitals were few and far between; consultation was difficult to procure, and laboratory diagnosis was hard to obtain, so that the country doctor of those days had of necessity to be more resourceful and self-sufficient and had to depend on his own observations and experience in the treatment of his patients. I can assure you from actual experience that it was far from romantic to be called out on a winter's night, during a raging snow storm in subzero weather, over roads covered with drifting snow, to minister to the ills of a rural patient often many miles away. Compared to that, the country doctor of today has a a very easy task.

President's Address before the Northern Minnesota Medical Association, Crookston, Minnesota, August 24, 1946.

When he receives a country call, he can step into his high-powered automobile and with very little discomfort speed over highways cleared of snow in the winter time to his patient's bedside, and make the round trip in one quarter of the time and with none of the hazards and discomforts required during the horse and buggy days. Or he can drive to a well-equipped modern hospital not many miles away, and arrive there as rapidly as some of the city surgeons, whose homes are in the fashionable suburbs, can reach the hospital with which they are affiliated.

Not only have there been great changes in the administration of a country practice since the dawn of the century, but there have also been great changes in the character of the human afflictions that the country physicians are called to treat. Some of the diseases that were common at that time are now very rare. Epidemics of small pox, diphtheria and typhoid fever were usually an annual event, and often took a great toll of humanity. Pulmonary tuberculosis was not considered contagious at that time, but was thought to be hereditary; and due to the poor housing conditions under which the early settlers had to live, frequently decimated entire families. Tuberculous disease of the bones and lymphatic glands, due to the bovine germ and transmitted to humans through infected milk, was very prevalent. Now, through the pasteurization of milk and the tuberculin testing of cattle that type of tuberculosis has been almost entirely obliterated. Thus through the progress of medical science and the discovery and use of vaccines and antitoxins to prevent and treat disease, many of the maladies of former days are almost non-existent.

In spite of the elimination of the hazard, hardships and inconveniences of country practice, the average graduate in medicine today does not choose to locate in the country, but usually prefers to establish himself in the larger and more populous centers where the profession is often overcrowded but hospital and facilities are near at hand. This migration to the cities has resulted in a real scarcity of physicians in the villages and rural communities. In fact, there are counties in some states without a single resident physician. Dr. Simons, our esteemed president of the Minnesota State Medical Association, in a recent issue of Minnesota Medicine, covered this situation very ably and very thoroughly. He stated that the lack of proper medical care in some parts of the country is not due to an actual shortage of physicians but to a lack of proper distribution of physicians.

This tendency of medical graduates to establish themselves in the larger centers is not only evident in our country but in other lands as well. In our neighboring country south of the border this tendency has been evident for a number of years—so much so, in fact, that Mexico City with its population of about two million has a large oversupply of physicians, while many parts of the republic lack adequate medical care. The government of Mexico has recognized this deplorable condition and has attempted to ameliorate it by appropriate legislation. Every graduate of a medical school in Mexico is now required to locate for six months to a year in a locality needing a physician before he receives his diploma, and during this period of probationary practice, the government assists him financially.

Another reason advanced by some as a factor in the cause of this mal-distribution of physicians in the country is the great increase of specialization. It is claimed that a number of medical colleges are devoting so much time to turning out specialists that the education of general practitioners is neglected. Years ago, when a doctor wished to become a specialist in medicine or surgery, he was advised to engage first in general practice for a few years so he could ascertain what line of practice he preferred and was best fitted for. Then, through personal experience he could better appreciate the problems and difficulties of a general practitioner.

In conclusion, I wish to say that the inadequate distribution of medical care in this country of ours is one of the chief arguments advanced by advocates of state medicine. It, therefore, behooves organized medicine to use its very best efforts to meet this problem and to see that this mal-distribution of doctors is corrected, so that all parts of our country are provided with proper medical care. In that way the time-honored relation between the doctor and his patient will be preserved, and the country doctor will not become a relic of the past and a forgotten man.

NEWER METHODS IN THE TREATMENT OF HYPERTHYROIDISM

ARNOLD S. JACKSON, M.D.
Madison, Wisconsin

WHILE thyroidectomy has long been considered a satisfactory method of treating adenomatous goiter, the surgical removal of the hyperplastic type has not afforded equally good results. Those interested in the study of goiter have long sought other means of overcoming hyperthyroidism in exophthalmic goiter. In the early part of this century, various solutions including weak phenol and boiling water were injected into the goiter in an attempt to destroy it; quinine, urea, and x-ray therapy had their day; and then in 1922 when Plummer proposed the pre-operative use of Lugol's solution, some advocated iodine as a curative measure, and unfortunately a few still continue to do so. Then George Crile suggested denervation of the adrenal glands, and others irradiation of the pituitary. In time all these methods were discarded, and thyroidectomy again returned to favor.

Still, thyroidectomy, even when performed by the most experienced thyroid surgeons, occasionally proves to be disappointing. Probably the incidence of recurrence for all surgeons performing thyroidectomy has been at least 10 per cent. In some patients two or even three recurrences have developed. I performed a thyroidectomy upon one patient with exophalmic goiter upon whom three subtotal resections of the gland had been performed previously by skillful surgeons.

As a consequence, because of these occasionally unsatisfactory results and because recurrences sometimes develop after many years of good health, the discovery of a real antithyroid drug was eagerly anticipated. Such a discovery seemed apparent when Astwood and others demonstrated in 1943 the effectiveness of thiouracil in treating hyperthyroidism.

Three years have now elapsed since Astwood's report, and thiouracil has been tried in many thousands of cases. At first the drug was released only to institutions prepared to conduct careful clinical research studies on its effect in hyperthyroidism. Despite these careful investigations, thirty or more deaths as a result of agranulocytosis are known to have occurred. Since the drug has been generally released, a certain number of unpublished deaths have undoubtedly occurred from its use. One of the most recent about which I have learned was a patient with neurocirculatory asthenia that had been incorrectly diagnosed as hyperplastic goiter.

Despite its unfortunate toxic effects, thiouracil has proved a valuable adjunct to surgery in the treatment of certain types of toxic goiter. Three years' experience in a series of fifty cases has led me to the following conclusions regarding the advantages and dangers of this antithyroid agent.

There are advantages in its use in the following types of cases:

1. In advanced multiple toxic adenoma in which there is no response to iodine.
2. In toxic adenoma complicated by such conditions as myocarditis, fibrillation, hypertension, diabetes, and decompensation.
3. In severe exophthalmic goiter, in the very young and in the aged and in the debilitated and decompensated.
4. In exophthalmic goiter in which because of pregnancy, previous nerve injury, infections, or other diseases it may be desirable to delay operation and yet not continue on iodine.
5. In "iodine-fast" exophthalmic goiter.
6. In recurrent or persistent hyperthyroidism.

Thiouracil has supplemented but not supplanted thyroidectomy in the treatment of toxic goiter. Because it in no way tends to reduce or eradicate the nodular adenomatous goiter, it cannot replace operation. The toxicity may be reduced and even controlled, but the goiter may still continue to grow and cause pressure symptoms or even become malignant. The fact that I have seen five adenomatous goiters in recent months that have undergone malignant changes has made me more cognizant than ever of this possibility. The experience of numerous other surgeons interested in this field indicates that malignancy of the thyroid is apparently on the increase.

The experience of a large number of investigators has been that, sooner or later, most of the patients with exophthalmic goiter who have been on treatment with thiouracil tend to have recur-

Read before the meeting of the Interurban Society of Duluth and Superior at Superior, Sept. 19, 1946.

rences. My own experience is negligible since I have preferred to use the drug largely as a preoperative measure in certain selected cases. Because of the danger of the development of agranulocytosis, because of the necessity of having patients travel a considerable distance at weekly intervals to have a check of the white blood count, and because of the comparatively long period of treatment and observation required, thyroidectomy has remained the treatment of choice for most patients. One patient with a mild case of exophthalmic goiter is now well eight months after the drug was stopped. Three patients suffering from a recurrence likewise appear cured after a similar interval. Ten suffered a relapse after the drug was stopped.

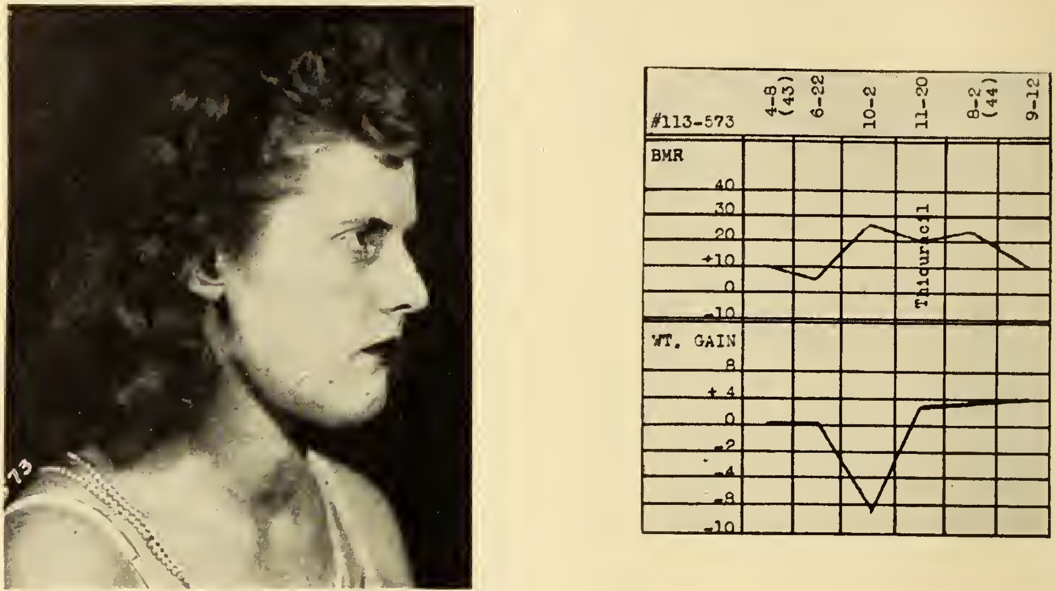

Fig. 1. Recurrent exophthalmic goiter with nerve paralysis controlled and apparently cured by thiouracil.

In such types of cases as have been previously mentioned, thiouracil has proved a most useful agent, and in my own experience it has occasioned no serious consequences. However, two mild skin reactions and one gastro-intestinal upset have occurred. Few reactions to the drug have occurred, I believe, because all patients have been schooled to watch for toxic manifestations and have been observed at short intervals and especially because the drug has not been used in large doses. Patients are usually started on a dose of 0.1 gm. three times a day, and this amount is seldom doubled. As soon as indicated by the metabolic rate and clinical study, the dosage is reduced to a maintenance amount of 0.2 gm. daily.

Five months ago I discontinued the use of thiouracil and began substituting a less toxic antithyroid agent, propylthiouracil. There is every indication that this new preparation will prove equally as effective as thiouracil in the treatment of hyperthyroidism and will be devoid of its danger. All patients who were receiving thiouracil have now been changed over to this drug, and their clinical status and metabolic rates remain equally satisfactory. On the other hand, there is little indication that propylthiouracil will prove of any greater curative value. For example, two children, aged nine and thirteen, both of whom have exophthalmic goiter, have been receiving these drugs for a year and both continue to show signs of hyperthyroidism, although the disease is held in check.

Propylthiouracil is still on a research basis, but there is every indication that it will shortly be released and will largely supplant thiouracil. It is my belief that thiouracil should never have been released for general distribution, and I believe it should now be withdrawn in favor of its less dangerous successor. However, the same precautions must be observed in using propylthiouracil, and frequent observation and checking of the leukocyte count should be continued until greater data is accumulated. It is dispensed in 25 mg. tablets, and the average dose is one before meals and one at bedtime. Some investigators have been using up to 150 mg. or more a day with no unfavorable reactions. One case of clinical agranulocytosis without serious consequences has been recorded. This report was by Dr. Bartels of the Lahey Clinic and was presented at the June meeting of the American Association for the Study of Goiter. This discussion concerned a study of 165 cases of hyperthyroidism treated by propylthiouracil. A study of eighty cases was reported by the Cleveland Clinic. The results achieved at these institutions and at the Jackson Clinic indicate that propylthiouracil will prove more effective than Lugol's solution in the preoperative preparation of patients having toxic adenomatous goiter. As with thiouracil, the poor risk patient may be so improved that a one-stage thyroidectomy may be performed with little danger. There is no indication as yet that this drug will do other than this in exophthalmic goiter. It may effect a cure without surgery in mild and incipient cases and possibly in a small percentage of the remainder.

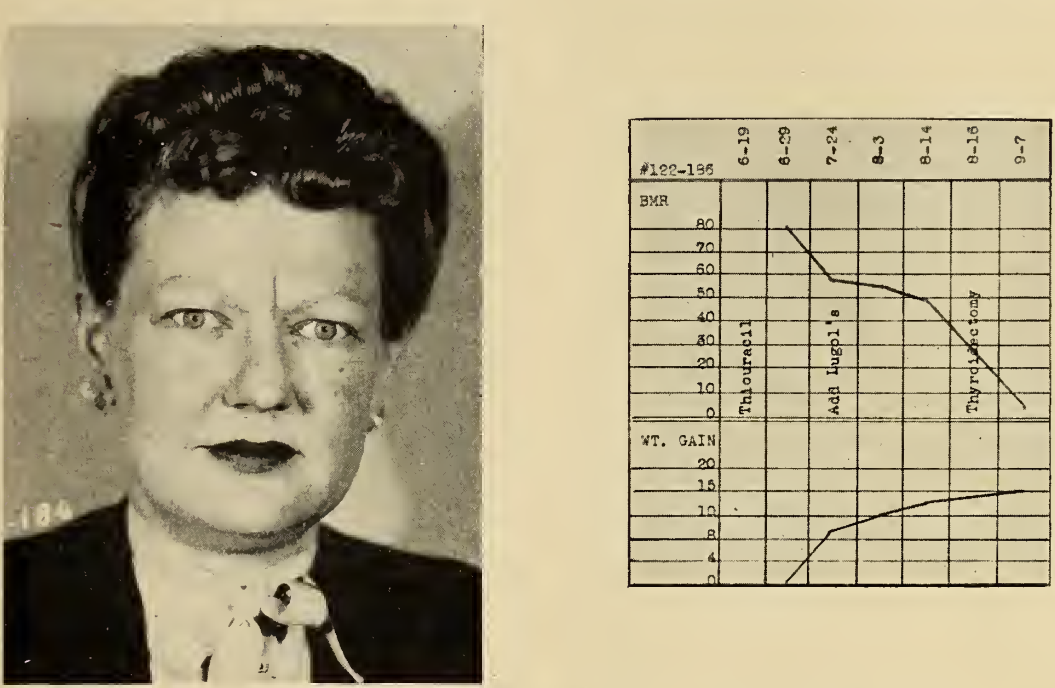

Fig. 2. A severe case of "iodine-fast" goiter responding well to thiouracil.

Preliminary reports by Drs. Hertz and Chapman of Boston on the use of radioactive iodine are interesting but inconclusive. In a small series of twenty-five cases of hyperthyroidism, satisfactory results were obtained in twenty, and in the remainder it was necessary to perform thyroidectomy to effect a cure. Reports by these brilliant young investigators presented at the Chicago meeting of the goiter society aroused the keen interest of all the members. The possible effect of radioactive iodine on carcinoma of the thyroid was discussed, but little was brought out to justify the exaggerated reports that have appeared in the press and which did not receive the approval of the investigators.

At the meeting of the goiter society, my brain became somewhat confused after two days of atomic bombing with isotopes, radioactive iodine and other new ideas in relation to goiter, but I finally gathered courage to present a nearly forgotten subject, the treatment of hyperthyroidism by thyroidectomy. A study of 100 cases of exophthalmic goiter operated upon twenty or more years ago was presented, and slides of several of these patients as they appeared in the early twenties and as they appear today were shown. Only one of these patients is suffering from the disease today, and in this case the symptoms are mild and under control. Ten of the patients are now over seventy-five years of age and are still in good health.

Newer methods in the treatment of hyperthyroidism are proving a valuable adjunct to the surgeon in treating hyperthyroidism, but as yet noth-

INTERNAL DERANGEMENT OF THE KNEE

MARK B. COVENTRY, M.D.
Rochester, Minnesota

THE TERM "internal derangement" has been employed since Heys first introduced it in 1784 to include a large group of intra-articular conditions of joints. Infections of joints and different types of arthritis *per se* are excluded from the group but most other lesions of the knee joint are included. The athlete who has a "trick knee" and the patient who says, "Doctor, my knee goes out of joint," are suffering from internal derangement of the knee. The patient usually contributes information which reveals that rather sudden mechanical locking, slipping or giving way of the joint occurred and that the subsequent reaction of the synovium was characterized by swelling. After a period, the condition usually becomes asymptomatic only to recur after subsequent trauma. A high percentage of patients who have internal derangement of the knee are young men because they are more likely to be subjected to trauma than are others.

Approximately twenty-five separate conditions may cause mechanical derangement of the knee. The two most common are tears in the semilunar cartilage and loose bodies in the knee. According to figures recently compiled by Henderson and Lipscomb,[3] 1,079 arthrotomies were performed in 1,031 cases at the Mayo Clinic before 1944, for treatment of conditions arising from tears in the semilunar cartilage or from loose bodies. Six hundred fifty-nine tears were found, and in 420 cases derangement was due to the presence of a loose body. The correct diagnosis was made pre-operatively in 79 per cent of the cases. In this unselected group, patients of all ages were included.

The diagnosis of internal derangement depends on the history, physical examination with special attention to the knee, roentgenographic examination and, in some cases, surgical exploration. Most important among these is the history. From the history it can be decided whether conservative or surgical treatment should be instituted. In taking the history, attention should be given to the type of attack—whether true locking has occurred, or whether simply a little catch or a giving way is responsible—to the number of attacks and to whether these attacks are getting more or less frequent. The triad of symptoms usually associated with internal derangement is pain, catching or locking, and swelling. According to Henderson and Lipscomb's statistics, 70 per cent of all of these patients had this triad. However, one or more of the symptoms may be lacking and it is important that the patient not be dismissed simply because locking has not occurred. In cases of tears in the posterior part of the cartilage or disruption of a ligament locking does not, as a rule, occur.

For examination after the general evaluation, the patient's lower extremities should be unclothed. The patient should first be asked to walk, so the presence or absence of swelling, of atrophy of the quadriceps femoris and of limping, and the range of motion, can be observed. The patient sits down for the rest of the examination. It is easier for me if I sit at a right angle to the patient. The patient is asked to point with one finger to the location of most of the pain. Then the knee should be palpated for warmth or tenderness. Sometimes loose bodies or the semilunar cartilage itself can be felt. The range of motion is observed, and at the same time the examiner can determine whether crepitus is present by placing his hand on the knee. Lateral and anteroposterior stability is then determined.

Following this roentgenograms should be taken and examined. The roentgenographic findings are of only negative significance in many cases. Tears in cartilage and injury to soft tissue will not be manifested in a routine roentgenogram. However, calcified menisci, loose osteocartilaginous bodies, osteochondritis dissecans and fractures of the tibial spine can all be seen by roentgenogram. Besides the conventional anteroposterior and lateral views, two special views are of great help in the diagnosis and localization of lesions of the bones of the knee.[2] (1) The intercondylar notch view taken with the patient's knee flexed reveals at times the presence of osteochondritis dissecans. Evidence of this condition cannot always be seen in other roentgenograms. This type of roentgenogram will also reveal loose bodies which may be caught in this region and injuries to the tibial

spines. (2) A vertical patellar view often will show evidence of osteochondritis and other abnormalities of the patella and the femoral condyles.

Diagnosis and Treatment of Specific Internal Derangements

An outline somewhat similar to the one presented by Badgley[1] follows. It is used for a brief description of diagnosis and treatment of specific internal derangements.

I. Semilunar cartilage.
    (a) Tears.
    (b) Cysts.
    (c) Congenital abnormalities.
    (d) Calcified meniscus.
    (e) Hypermobility or recurrent dislocation.
II. Lateral ligaments.
    (a) Rupture.
    (b) Cysts and adventitious bursae.
III. Injury to cruciate ligaments.
IV. Loose bodies.
    (a) Of synovial origin.
    (b) Of articular origin.
        (1) Osteochondritis dissecans.
        (2) Osteochondral fractures.
V. Soft tissue.
    (a) Adhesions.
    (b) Hypertrophic infrapatellar fat pads.
VI. Recurrent dislocation of the patella.
VII. Fractures of the tibial spine.

Semilunar cartilage.—The tear of the cartilage may be in the anterior, medial or posterior third, or may be of the so-called bucket-handle type. In the bucket-handle type the most severe locking occurs, and reduction with the patient under anesthesia sometimes is required for treatment. Diagnosis is based on a history of injury, locking, swelling and pain, and on physical examination either at the time of injury or later. Tenderness is almost always present over the injured cartilage and sometimes a definite click can be felt on flexion and rotation of the tibia on the femur. Treatment consists of excision of the cartilage. In my opinion, the entire cartilage should be removed, preferably through two incisions.

Cysts are probably congenital. They almost invariably occur on the lateral meniscus, and the swelling can be seen cephalad and slightly anterior to the fibular head. Catching and pain are often present and treatment is excision.

The "discoid" meniscus is the most common congenital abnormality. It usually involves the lateral meniscus. Diagnosis is made chiefly by means of the history. Patients who have this congenital abnormality have had "snapping knee" since childhood and pain in the region of the lateral meniscus. It is treated by surgical excision of the meniscus.

Calcified meniscus is found fairly commonly in older patients, and, as a rule, produces a few symptoms. Only occasionally do swelling and catching occur. I have encountered one case of true locking. If locking does occur, the meniscus should be excised; otherwise, conservative measures, including diathermy, should be used.

While hypermobility or dislocation without tear may be found, it exists less commonly than is generally thought. Usually it can be demonstrated at the time of operation that the anterior third of the cartilage is hypermobile. If the condition which arises in cases of hypermobile cartilage is severe enough to cause locking and swelling, the cartilage should be excised.

Lateral ligaments.—Either the tibial or the fibular collateral ligaments may become ruptured. The history of injury is always given. If the relaxation is only mild, the best treatment is to build up the quadriceps muscle. If the entire ligament is definitely disrupted, the defect should be repaired surgically.

Cysts and adventitious bursae occur with some frequency, and the diagnosis is often made only at the time of operation because the condition which arises in these cases resembles that in cases of torn cartilage or cyst of the cartilage. If a cyst is present it should be removed. Roentgen therapy or diathermy and injection of procaine hydrochloride should be used for treatment of adventitious bursae, and surgical treatment should be carried out only as a last resort.

Injury to cruciate ligaments.—Both the anterior and the posterior cruciate ligaments may be injured. Injuries of this type commonly occur in automobile accidents in which the patient's knees are bumped against the dashboard. While surgical procedures have been devised to repair the injuries, if the quadriceps femoris is strong and the collateral ligaments intact, tears in the anterior and posterior cruciate ligaments are not particularly disabling. Treatment should be directed toward restoration of strength in the quadriceps muscle which is invariably weakened.

Loose Bodies.—Cure in cases of osteochondromatosis in which loose bodies are derived from synovia, can be accomplished only by complete synovectomy. If but one or two loose bodies are present, however, these can often be removed and the patient will experience a good deal of permanent relief. Loose bodies should be removed, for their presence tends to traumatize the articular cartilage, and irreversible changes in the hyaline cartilage occur.

Osteochondritis dissecans, in which loose bodies are derived from the articular cartilage, is found most frequently in young men. In its early stage it is diagnosed when pain and swelling occur. Later when the dead fragment of cartilage and bone separates and becomes a loose body, locking frequently occurs. It is treated by removal of the loose body. The bed from which the loose body separates is usually curetted down to bleeding bone at the same time, although there is some reason to think that this may not be necessary.

Osteochondral fractures may occur as the result of a direct blow to the patella which transmits the blow to the femoral condyles, or of a direct blow to the femoral condyle itself. In cases of osteochondral fracture, patients must be observed carefully for evidence of necrosis of bone and cartilage.

Traumatic and hypertrophic arthritis with detached osteophytes is encountered frequently in elderly patients and, when locking occurs, the best treatment is surgical excision of the loose bodies.

Soft tissue.—Adhesions may occur after an intra-articular fracture with hemarthrosis. They prevent full range of motion and the adhesions usually must be cut surgically as they often are extremely strong and cannot be broken by manipulation carried out with the patient under anesthesia.

Hypertrophic infrapatellar fat pads will be found occasionally. The pads become pinched between the femur and tibia and cause catching, pain and effusion. If the symptoms warrant, surgical removal of the fat pads should be carried out.

Recurrent dislocation of the patella.—Diagnosis of this condition is often missed because an inadequate history has been taken. The patient should be questioned carefully as to whether he has seen his knee when it "goes out of joint." Sometimes it is so painful the patient does not think about how the knee looks, but as most dislocations of the patella are lateral and are observed easily even by the untrained eye, information concerning the episodes usually will help the physician make the diagnosis. In other cases, the physician sees the dislocation, for frequently it must be reduced with the patient under anesthesia. Treatment should be carried out early to prevent the occurrence of secondary arthritic changes in the knee and is directed toward reattaching the patellar tendon medially and distally. This treatment is satisfactory in most cases although occasionally fascial slings must be used in addition. In cases in which the lateral femoral condyle has flattened it must be raised by means of a wedge osteotomy.

Fractures of tibial spine.—These occasionally occur because of either anterior or posterior strain. The tibial spines are avulsed because of the pull of the cruciate ligaments. For treatment a cast is applied and usually patients recover satisfactorily. Careful observation is necessary so non-union or avascular necrosis of the spines may be found when it occurs.

Comment

In conclusion I would like to emphasize three points:

1. The main disability in all internal derangements of the knee is weakness of the quadriceps femoris and nothing in the way of a cure can be achieved unless the quadriceps is brought back to normal. This cannot be done simply by having the patient walk, but a systematic program of exercises against weight must be carried out preoperatively and postoperatively or, if surgical treatment is not undertaken, during the convalescence from the injury.
2. In cases in which removal of semilunar cartilage is necessary, the entire semilunar cartilage should be removed, not just the anterior two thirds. It has been my experience that catching and pain are produced occasionally by the posterior third of the cartilage when it is left.
3. In any case in which it is necessary to perform arthotomy the patient should be assured

(Continued on Page 83)

RECTAL IMPALEMENT

Report of an Unusual Case

C. T. EGINTON, M.D., M.S. (Surg.)
Saint Paul, Minnesota

WOUNDS of the rectum by impalement are of infrequent occurrence; however, they are of interest because of the frequently bizarre accidents from which these injuries are sustained, the extensive damage often done to contiguous tissues, and the serious danger of peritoneal contamination.

During the past few years there have been reports of an occasional case or small series of cases of traumatic perforations of the rectum, most of these being due to instrumentation, enemata or air pressure. Reports of injury by impalement have been quite rare. This particular trauma is apparently primarily a haying hazard, most of the reported cases occurring in farmers who have fallen from hay stacks onto pitchforks, rakes, or other farming implements. However, miners, well-drillers, and, in fact, nearly all industrial workers are occasionally subject to this type of injury.

I wish to report a case of rectal impalement unusual in respect to etiology as well as involvement of adjacent structures.

Case Report

H.M., a twenty-year-old Thlingit Indian, male, was brought to the Whitehorse General Hospital, Whitehorse, Yukon Territory, Canada, at 11:30 p.m., December 13, 1945, complaining of intense abdominal pain and bleeding from the rectum. At 2:30 p.m. that day, returning from his trap line near Teslin Lake, Y.T., he was standing on a toboggan type sleigh behind his dog team. As the descent to the lake down a steep bank commenced, the dogs got out of control and left the trail. When the patient noted that the sled was headed for a clump of bushes, he attempted to sit on the sleigh and control its course by dragging his feet in the snow. As the toboggan tipped to one side he was thrown clear and landed on a branch of wood about two feet long and about one inch in diameter. At the time of this accident the dog team was travelling at high speed, probably about twenty miles per hour. He was impaled on this piece of wood with very great force. The branch penetrated his rectum and the patient thought it broke off as he heard a distinct snapping sound. He lost consciousness, however, immediately afterward. When he regained consciousness, the dog team was over half way across Lake Teslin, which would take between eight and ten minutes with the team travelling at twenty miles per hour. The patient extracted the stick from his rectum and began to walk to his camp, a distance of two miles. This walk was through deep snow and required great effort. He arrived at his camp about 4:30 p.m. and remained there until 6 p.m. when the Royal Canadian Mounted Police car arrived and transported him to Whitehorse, a distance of 114 miles. He was admitted to the Whitehorse General Hospital at 11:30 p.m., nine hours after the injury. There had occurred a moderate amount of bleeding from the rectum during this period. The pain in the rectum had intensified and had now become associated with severe abdominal pain, most marked in the suprapubic area. Shortly after admission to the hospital, he passed about 200 c.c. of bloody urine. There was no dysuria, and no gas was noted in the urine.

Physical examination at the time of admission revealed a well-developed, well-nourished Thlingit Indian male, in acute distress, conscious and rational, lying in supine position. Blood pressure was 100/70, heart rate 84, oral temperature 103°F. The entire abdomen was rigid and tender, most markedly below the umbilicus. There was no distention, but the abdomen was silent to auscultation. There was a ragged superficial abrasion in the anterior part of the anal skin extending into the mucosa. Digital examination revealed a perforation in the anterior wall of the rectum about 9 or 10 cm. from the anus. There was a small amount of semi-solid fecal material in the rectal ampulla.

Ten hours after the injury, the patient was taken to the operating room. With the patient in the Sims position, a proctoscopic examination under spinal anesthesia showed a ragged rent in the anterior rectum about 10 cm. from the anal margin. It was about 4.5 cm. long and gaped about 2 cm. Through this could be seen a loop of small bowel surrounded by fecal material. The perforation extended through the rectovesical pouch of Douglas into the posterior wall of the bladder (Fig. 1). There was no leakage of urine apparent at this time and it could not be determined if the bladder mucosa was intact. Several large fecal masses were removed from the pouch of Douglas with sponge forceps and suction; the rectal perforation was closed with four interrupted No. 0 plain catgut sutures. The patient was then placed on his back. A left paramedian incision was made below the umbilicus, splitting the rectus muscle. Upon incising the peritoneum, a moderate amount of sanguineous stercoraceous material was encountered. As much as possible of this was removed by suction and sponging. The pelvis was explored and the peritoneal tear was closed and anchored above the ecchymotic area on the posterior wall of the bladder. Perforation of the bladder was not demonstrable at this time, so no sutures were placed in the bladder. However, the damaged area was covered with peritoneum from the cul de sac. A loop of sigmoid colon was brought into the abdominal incision; the two pillars were sutured together for a distance of 8 cm. and were anchored laterally to avoid fenestration, and the abdomen was closed.

On December 15, 1945, the colostomy was opened with the cautery. Borborygmi were audible on that day. The patient's general condition improved rapidly; however there occurred frequent watery stools with a uriniferous odor through the rectum and colostomy.

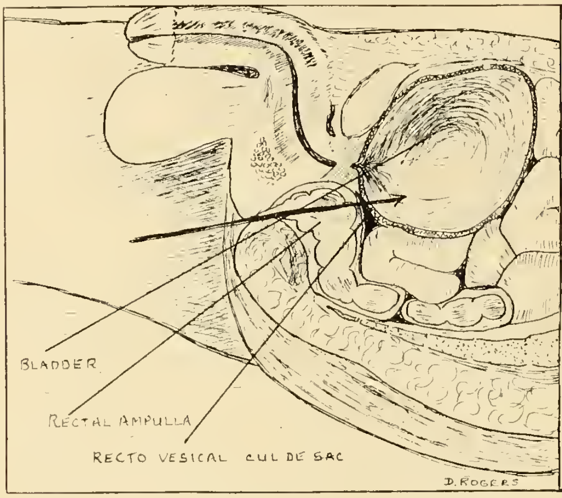

Fig. 1. Sagittal section shows path of impalement.

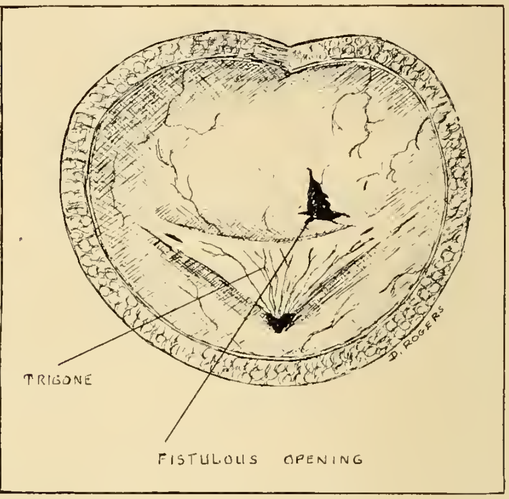

Fig. 2. Posterior wall of bladder.

Cystoscopy was performed on December 27, 1945, when it was deemed that the patient's general condition warranted such a procedure. No obstruction to the insertion of the cystoscope was encountered. The bladder was filled with cloudy urine containing flecks of mucopurulent material. The mucosa over the entire posterior wall and trigone was uniformly reddened and edematous. The ureteral orifices appeared normal. There was a large ragged perforation, 2 by 1 cm., triangular in shape, in the retroureteral pouch, about 2 cm. above the trigone ridge. The edges of this tear appeared necrotic. Fluid could be seen to run directly into the rectum and cloudy fluid return. It was possible, while clear fluid was running into the bladder, to visualize the lumen of the rectum through the fistula (Fig. 2).

On January 4, 1946, the patient was again taken to the operating room where spinal anesthesia was induced. He was placed in an exaggerated lithotomy position, and a transverse, curved incision was made 2 cm. anterior to the anus. This was carried down through the perineal body; and the rectourethralis muscle was transected. Denonvilliers' fascia was dissected, exposing the fistula above the prostate. The rectum was mobilized well above this area. The fistula was then excised and the edges of the bladder defect freshened with the scalpel, and the muscular layer of the bladder was united with chromic No. 00 catgut continuous suture, avoiding the mucosa. Denonvilliers' fascia was approximated over the bladder suture line with another row of interrupted sutures. The levator ani leaves were pulled together in front of the rectum with three interrupted sutures of chromic No. 1 catgut. The mobilized rectum was pulled toward the anus as far as possible, the first, most superior suture, being carried into the anal sphincter to anchor the rectum in its anal position. The redundant rectal mucosa was excised and the remaining defect closed with a continuous suture of No. 00 chromic catgut. The perineal muscles were reunited with plain No. 0 catgut interrupted sutures and the skin was closed with subcuticular plain No. 0 catgut. An urethral catheter was left inlying.

No leakage occurred at the site of repair, the wound healed primarily, and the patient recovered without incident from this operation. On January 19, 1946, a clamp was applied to the colostomy spur. On January 26, 1946, the inlying catheter was removed and the patient began voiding spontaneously four to five times each day. The bladder apparently had normal capacity. The colostomy spur was completely obliterated by January 28, 1946. Urinalysis on February 4, 1946, was negative. On February 5, 1946, cystoscopy was again performed. There was no cystitis; the urine was clear. At the site of the previous fistula, there was only a dimple in the mucosa, completely healed. Four hundred c.c. of 12 per cent sodium iodide solution were instilled into the bladder and a cystogram taken. This showed no leakage into the rectum. The bladder outline was normal except for a very slight denting at the site of the former fistula. Digital examination of the rectum showed firm non-tender scar tissue. On March 8, 1946, the patient was returned to the operating room. Under intravenous sodium pentothal anesthesia, the colostomy was closed extraperitoneally. The peritoneum, however, was undermined and pulled over the suture line in such a manner that a sling for the sigmoid loop was formed. Thus it was possible to close the abdomen firmly in layers, including the peritoneal folds. Recovery was uneventful, and the patient began having normal bowel movements in four days.

(Continued on Page 61)

CHYLOTHORAX: PREGNANCY IN AN ARRESTED CASE

GUS EDLUND, M.D.
Saint Paul, Minnesota

CHYLOTHORAX is an effusian of chyle in the pleural cavity due to lesions of the thoracic duct or of its radicals. It is a relatively rare condition and often of obscure etiology. Thirty per cent of the cases are said to be due to trauma, 18 per cent to cancer of the pleura, 15 per cent to occlusion of the left subclavian vein, 7 per cent to compression of the thoracic duct, 7 per cent to sclerosis of lymph vessels, 7 per cent to lymphangiectasis, and 16 per cent to malignant lymphoma and blood parasites (probably filaria).[5] Mortality is high, being somewhat less than 50 per cent.[4] This is readily understood when the etiology is taken into consideration. According to Brescia,[1] Bartolet first described this entity in 1633. Hoyer[2] reported the eighty-fifth case in 1938, and in 1944 Jahsman[3] reported three cases, bringing the total number up to 105.

Case Report

The case I wish to report, the first pregnancy in an arrested case, is that of C.E.D., a white woman, aged thirty-one, first seen on January 18, 1943, when she complained of gastric distress, anorexia, menorrhagia and malaise.

She had had lobar pneumonia in 1933 and said she had not felt well since. She also had an uncomplicated appendectomy in 1937. Physical examination at that time revealed a normal chest. There was some tenderness in the right mid-abdomen, and the uterus was fixed in the right pelvis. The hemoglobin was 70 per cent. No definite diagnosis was made but she was put on a tonic regime and responded so well she was discharged February 9, 1943.

On June 1, 1943, I was called to her home and found her confined to her bed with a history of having had a "cold" for a week or so. She looked very sick, and casual examination revealed lungs full of moist râles with the left chest half full of fluid. She was sent to Midway Hospital by ambulance and was admitted with a temperature of 101.8° which rapidly went up to 104°, and then quickly subsided under sulfathiazole.

On admittance, urine showed 2 plus albumin, hemoglobin 58 per cent, Wassermann negative, RBC 4,240,000, WBC 10,600 with normal smear and differential count. X-ray of the chest showed considerable increased density in the left base due to effusion, and the heart was displaced to the right. There was no evidence of lung or mediastinal infiltration. On June 3, 1943, a re-ray with horizontal and vertical left lateral views of the chest showed a freely shifting effusion.

On June 4, I aspirated 700 c.c. of milky fluid which was alkaline in reaction and had a specific gravity of 1.014. Culture showed a few Gram-positive diplococci. Guinea pig inoculations were reported negative on July 17 and July 30. Re-ray of the chest showed considerably less effusion in the left basal area than on the previous study, with considerably less displacement of the heart to the right. A moderate degree of effusion still remained basally on the left. No definite lung infiltration was demonstrated.

Fluid gradually re-formed in the left chest, and on June 12 respirations were again embarrassed and 800 c.c. of milky fluid were aspirated. Re-ray showed no change except possibly a slight decrease in the fluid densities in the left base.

Feeling that we were accomplishing nothing by aspiration and were only wasting previous body fluid, we pursued an expectant course, but had to aspirate her again on June 18 because of marked respiratory embarrassment. Fluid became less and less and finally was entirely absorbed as verified by x-ray examinations which revealed the heart normal in size and configuration, the lungs entirely normal with evidence of adhesive pleurisy in both costo-phrenic angles.

On June 20, 1945, two years after the last aspiration, she returned to my office feeling fine but thought she might be pregnant, her last menstrual period having been on May 5, 1945. Examination at this time revealed a normal chest and abdomen, blood pressure 130/80, hemoglobin 84 per cent, urine 2 plus albumin, and a positive Friedmann test. The question then arose as to what advice to give her. She was very anxious to have a baby and her husband felt the same way. A search of the literature revealed no record of pregnancy following chylothorax. I finally decided to adopt expectant treatment, feeling that if we could bring the fetus to viability without too seriously endangering the mother we could do an elective cesarean section and avoid the strain of labor.

Dr. McKelvey, head of the department of obstetrics at the University of Minnesota, became interested in the patient, and in October, 1945, I sent her to the University Hospital at his request for observation and study with particular reference to vital capacity studies.

His report of October 20, 1945, was as follows: blood pressure on admittance 156/98, on the following day 134/76 and on the day of discharge 138/90. A catheterized urine specimen showed 2 plus albumin and occasional white blood cells, and hemolytic streptococcus was cultured from it. Uric acid was 4.6 mg. Other chemistry reports were normal. The venous pressure was 11.5 cm. of saline. Circulation time was, arm to tongue, 15 seconds, arm to lung 5 seconds. An electrocardiogram was normal. An accurately measured vital capacity was 2.88 liters. Chest x-ray showed an old adhesive pleurisy. The blood cholesterol was 390 mg. per cent.

Presented at the meeting of the general staff of Midway Hospital, Saint Paul, Minnesota, June 5, 1946.

Dr. McKelvey's conclusions were: "The patient has a mild pregnancy toxemia. There is no evidence of active chylothorax at present and no evidence of disturbance of pulmonary circulation or of the heart as a result of the previous episode. I have not been able to find any case report in the literature of a pregnancy association with chylothorax. However, in my opinion, there is no good reason to believe that there should be any change from the present state as a result of the pregnancy."

Her course from here on was uneventful except for varying rises and falls in blood pressure and varying amounts of albumin in the urine, until December 7, 1945, when her blood pressure was 150/90, albumin 4 plus, hemoglobin 70 per cent, and she did not feel very well. I ordered her home to bed. On December 14 she complained of severe epigastric pains and felt miserable. I had her admitted to Midway Hospital on that day and administered morphine for relief of pain. We were then in a position to weigh her every day and check her intake and output, blood pressure, fetal heart tones, and urine, hoping to delay a cesarean section as long as possible, as she was still two months from term. Her blood pressure ran fairly constant, about 150/90, and urine specific gravity was 1.012 to 1.016, with a constant 4 plus albumin and occasional white blood cells. Hemoglobin was 9.9 gm., Rh factor positive, urea nitrogen 26.5 mg., and uric acid 7.5 mg.

On December 18, Dr. Louis Freidman, who had been instrumental in interesting Dr. McKelvey, saw her and his impression was that she was suffering from a toxemia of pregancy, pre-eclampsia and secondary anemia, and advised continuance of conservative treatment in an effort to increase the viability of the fetus.

On December 27, 1945 (due February 12, 1946), her condition not having improved, I did a classical cesarean section, incising the abdomen under novocaine infiltration and the uterus under sodium pentothal anesthesia. The placenta was found attached to the anterior uterine wall. A male child weighing 4 pounds 8 ounces was delivered, the placenta extracted, uterus closed, tubes ligated and abdomen closed without drainage.

Before operation her blood pressure was 158/104, with fetal heart tones 136, urine 4 plus albumin, hemoglobin 10.4 gm. The pre-operative diagnosis was pre-eclampsia with arteriosclerosis. Postoperatively she was given 500 c.c. of whole blood, and this was repeated on January 3, 1946. Her postoperative course was uneventful and she was discharged from the hospital on January 10 with a blood pressure of 146/84; urine was alkaline, amber colored, specific gravity 1.016, 4 plus albumin, 3 to 5 R.B.C., 15 to 25 W.B.C.; hemoglobin was 12.4 gm.; temperature was 98.4°, pulse 88, and respirations 18.

The baby, weighing 4 pounds 8 ounces at birth lost 3⅛ ounces during the first three days and then gradually gained, until on discharge from the hospital January 31, he weighed 6 pounds 9 ounces. Six months following birth he was perfectly normal and steadily gaining in weight. The mother has been perfectly happpy, feels well, does all her own work but still has a blood pressure of 140/90, 4 plus albumin and 70 per cent hemoglobin.

Summary

1. In this case we were unable to establish an etiological factor for the chylothorax.

2. The relative rarity of the condition is emphasized by the fact that this is the 106th case reported and the first of pregnancy in an arrested case.

3. Diagnosis is dependent on aspiration of chylous fluid.

4. In this case we achieved arrest of the chylothorax by rest and supportive measures and by discontinuing aspiration. Pregnancy was treated conservatively and by elective cesarean section.

5. Evidently the pregnancy had no effect on the chylothorax nor the chylothorax on the pregnancy in this case.

Discussion

Dr. L. L. Freidman: This case is a most interesting one, and apparently very rare. A thorough search of the literature did not reveal a single case of pregnancy with chylothorax.

No specific conclusions from an obstetrical standpoint can be drawn from this case. Certainly the pregnancy did not influence the chylothorax, and I don't believe the chylothorax influenced the pregnancy, except from an increase in respiratory embarrassment during the last few weeks. Unfortunately, the patient developed a pre-eclampsia. She was put to bed and not only did not improve, but her diastolic blood pressure increased and urinary findings persisted on absolute bed rest.

Dr. Edlund sectioned this patient at viability. Undoubtedly without the toxemia she could have been allowed to deliver normally.

The toxemia may be classified as an arteriosclerotic superimposed with pre-eclampsia. We have no direct evidence of this, except a persistent albuminuria prior to pregnancy and a resultant hypertension and albuminuria three months postpartum.

This is a most interesting case, and so rare that it may be called an academic curiosity. I have urged Dr. Edlund to prepare the case report for publication, which he has so ably done.

OBSERVATIONS ON A MILD FORM OF EPILEPSY

LT. C. M. JESSICO, MC, USNR, LT. COMDR. K. H. FINLEY, MC, USNR, and
LT. COMDR. T. W. RICHARDS, HS, USNR

This is a report of studies made in the U. S. Naval Hospital, San Leandro, California, on patients who were returned to the United States from the Pacific area because of a history in which convulsive seizures were described or suggested. Though a large proportion of naval and marine patients suspected of having epilepsy while overseas were sent to this particular hospital, it was necessary to restrict the present report to a relatively small number.

For the most part, the studies made can be divided into four groups: (1) physical, neurological, psychiatric and laboratory examinations plus observation on the ward; (2) the water-pitressin test (as introduced by McQuarrie[7,8]); (3) psychological examination, and (4) electroencephalography.

Obviously, an epileptic history and a record of a previous diagnosis of epilepsy were important criteria in making the final diagnosis. However, we felt that without confirmation by means of at least one of these four methods of study, the final diagnosis of epilepsy should not be made.

Of the four approaches to the patient mentioned, the first—that of physical examination, et cetera—needs no further description. It might be well to discuss briefly each of the remaining procedures.

The water-pitressin test involves hydration with fluids by mouth, and antidiuresis by the use of pitressin parenterally. It has been shown that a convulsion can thus be induced frequently in an epileptic but not in a non-epileptic.[8] The mode of action is not understood but may be an alteration in intracellular and extracellular electrolytes since sodium chloride inhibits a convulsion.[8] The test, as standardized at this hospital, includes the oral intake of 500 c.c. of fluid every hour for eleven hours or a total of 6,000 c.c., and then every two hours for ten hours making an additional 2,500 c.c. Pitressin, 0.5 c.c., is given parenterally every two hours for a total of ten injections. If a grand mal seizure occurs at any time, the test is discontinued.

Psychological examination consisted of the following tests: Thematic Apperception Test, Rorschach, Minnesota Multiphasic Inventory, parts of the Bellevue-Wechsler Scale and the Cornell Selectee questionnaire. We were interested in the personality pattern and in detecting signs of psychological deficit which might be associated with deterioration.

Electroencephalograms were obtained on all the patients and were classified as normal, borderline* or abnormal. A six-channel Grass electroencephalograph was used. Eight electrode placements (four over each hemisphere: frontal, postfrontal, parietal and occipital) constituted the routine procedure used. The bipolar method of recording was employed. When the clinical history or other laboratory findings indicated, ten to sixteen electrode placements were applied. A two to three minute period of hyperventilation was employed in every instance, and a glass of fruit juice was given the patient one-half hour before the test.

This report covers seventy-three consecutive cases admitted to the neurology ward with a diagnosis of epilepsy. Except for the case of one man on whom the water-pitressin test was not made, each was subjected to the four methods of study described above.

The final diagnoses established for the group of seventy-three patients were:

Epilepsy	57
Psychoneurosis, otherwise unclassified	6
Hysteria	3
Personality disorder	3
Mental deficiency†	1
Narcolepsy	1
Migraine	1
No disease	1

Though not typical because of the great number of seizures, the manner in which the patients were

Dr. Jessico is now associated with the Duluth Clinic, Department of Neuropsychiatry, Duluth, Minnesota.

*Borderline is used for the types of EEG patterns which cannot be readily grouped as either definitely normal or abnormal. These borderline tracings include, for the most part, the following types of patterns: (1) low amplitude records which show no definite frequency at the standard rate of amplification (i.e., 50 microvolts when equivalent to a vertical deflection of the needle a distance of one-half centimeter); (2) tracings which show occasional random, medium or high voltage, slow cycles throughout; (3) records with the more than average number of low amplitude (less than 25 microvolts) 18 to 30 per second cycles, and (4) tracings containing an abundance of high voltage (over 25 microvolts) 18 to 30 per second cycles, usually occuring in random distribution rather than in paroxysmal bursts of rapid activity, which latter are included under the abnormal group.

†If a patient had mental deficiency and epilepsy, the final diagnosis was epilepsy.

studied is exemplified by the following summary of a case:

M. R., twenty years of age, was on active duty for one year and seven months before he was admitted to the sick list. He was overseas for one year and had combat experience.

He was admitted to the hospital in May, 1945, with the complaint of "spells of blackout" two or three times a year since about thirteen years of age. In some spells, he bit his tongue. Usually he had a sufficiently long warning so that he could hide before he lost consciousness. In April, 1945, he had a spell in the presence of naval personnel and awoke to find himself in sick bay. In this hospital, he gave a further history of "blank" episodes of a few seconds' duration once or twice a week since January, 1945, and intermittent left-sided headaches during the past year.

In the family history, it was learned that the mother was nervous and the father had trouble with his back. The patient had one sibling, a sister, who died of a mastoid complication at the age of twenty-three years. A maternal grandmother probably had epileptic seizures and later died of cancer of the breast. Two cousins had had convulsions.

The patient gave a history of a normal birth and the usual childhood diseases, including scarlet fever. He considered himself well except for the "spells." He bit his nails until shortly before admission. His home environment was unsatisfactory because his parents did not get along well together and there was a "funny atmosphere around home." He was expelled from high school once and quit school at the age of seventeen years. He has not married. Before enlistment, he worked in garages and traveled with a carnival. He drank considerable liquor overseas.

The physical and neurological examinations were essentially negative. Psychiatric examination revealed a restless, apprehensive, mildly depressed young man who worried over what people would think of him because of his spells. Psychological tests showed the man to have average mental capacity. The Rorschach revealed considerable anxiety and suggested a strongly traumatic background. The electroencephalogram was abnormal by virtue of the ease with which the pattern broke down to over-breathing and by a suggestive spike and wave contour of some of the slow cycles. Roentgenograms of the skull were negative. Routine laboratory examinations, which included a urinalysis, complete blood count and a blood Kahn, were negative.

On June 2, the patient had a grand mal convulsion witnessed by a nurse. On June 13, a grand mal convulsion was induced by the water-pitressin test after four injections of pitressin. Dilantin sodium, 1 gm. twice daily, was prescribed.

The age of the entire group ranged from seventeen years to forty-two years. A history of seizures prior to enlistment was elicited in those with a final diagnosis of epilepsy in thirty-four cases (60 per cent), and of these, eight said they had had only one attack. Of the twenty-three cases with a history of no seizures prior to enlistment, six had only one attack prior to admission to this hospital. Three of the established cases had only petit mal attacks, and the rest had grand mal seizures either alone or in combination with other forms. (It is not unlikely many petit mal cases have been unrecognized in the service.) The age of the first spell ranged from infancy to forty-two years. All but two had the first seizure before the age of thirty years.

Fourteen of the entire group had had actual combat experience, and twelve of these had had an established diagnosis of epilepsy. Nine had combat experience before the first seizure but no relationship could be determined. No individual in this series had seizures which suggested very strongly a relationship to head trauma. One patient had his first seizure one month after he was dazed by a blow to the head. Of the entire group, forty-three gave a history of head trauma of varying severity, and of those with the final diagnosis of epilepsy, thirty-two gave such a history, so that a larger percentage of the established cases of epilepsy gave such a history than those of the entire group. A few inconclusive abnormal neurological signs in several patients were discounted because of lack of supporting evidence of an organic lesion. Pneumoencephalograms on three patients were normal. It was impossible to make a worthwhile estimate of the effect of alcohol on the epileptic seizures. However, three claimed they had seizures only after heavy drinking. Of the entire group, a history of what might be termed a severe illness was elicited in sixteen, which included two cases of dengue fever. There appeared to be no relationship, except possibly for the two patients who had dengue fever and had their first seizure within a year of that illness. A family history of fainting spells or epilepsy was elicited in 39 per cent of the entire group and in 37 per cent of those with the final diagnosis of epilepsy. The figures were reversed slightly when only the terms epilepsy or convulsions had been used, and then 22 per cent of the entire group and 23 per cent of the definite epileptics had a positive family history.

In 40 per cent of those finally diagnosed as epileptic, a routine psychiatric examination had revealed evidence of mental deficiency or a personality disorder of sufficient degree to disqualify the individual for an early return to duty in the service. Results of the psychological tests suggested that of this group of fifty-seven men, forty-two gave evidence of appreciable maladjustment. Eight patients showed signs of psychological deficit. Six were mentally deficient. In fourteen cases, trends in the direction of possible psychotic development were in evidence. It must be pointed out that these men had been under the stress of overseas duty during the war. A relationship between the epileptic seizures and personality difficulties was not obvious, but a direct study of that problem was not made.

Electroencephalograms on the group of established epileptics were definitely abnormal in only 54 per cent of the cases. Another twenty-eight per cent were borderline. The following table gives the percentage of normal, borderline and abnormal records in this group of epileptics as compared with a larger group studied in civilian life.[4]

	Normal	Borderline	Abnormal
Military Group:			
1. Admission diagnosis of epilepsy (73 patients)...	30%	26%	44%
2. Final diagnosis of epilepsy (57 patients)	18%	28%	54%
Civilian Group:			
1. Final diagnosis of epilepsy (626 patients)	15%	10%	75%

In the military group, the seventy-three individuals admitted to the hospital with a question of epilepsy had a lower percentage of abnormal EEGs than the fifty-seven where such a diagnosis was later established. However, the military group of established epileptics had a lower percentage of abnormal EEGs than the civilian group, which implies that the convulsive states of the military group were of a milder character.

There was nothing consistent in the character of the abnormal EEGs. Most of them contained slow cycles of varying frequencies and about one-fourth had organized rapid cycles (frequencies between 18 to 30 cycles per second) usually with slow activity. In only one of the seventy-three cases was a typical spike and wave pattern obtained. Yet, several of the patients had petit mal attacks, although all but three had grand mal seizures also.

It is important to note that almost 50 per cent of the cases given a final diagnosis of epilepsy had normal or borderline EEGs. This demonstrates that a diagnosis of epilepsy is not ruled out by a normal EEG. Also a few questionable cases, in which the diagnosis of epilepsy was ruled out, had abnormal EEGs, confirming the fact that an abnormal EEG is not in itself proof of epilepsy. Like most laboratory tests, the EEG should only be evaluated when considered in the light of other clinical and laboratory findings.

Seventy-two out of the seventy-three cases had a water-pitressin test. The test was not completed in six cases. In thirteen, a grand mal convulsion was induced. Not excluding the incomplete tests, twenty-three per cent of the patients with the final diagnosis of epilepsy had a positive test. Twitching movements of the extremities occurred in four more. The diagnosis of epilepsy was made in three of these. In a previous group, which included forty-four cases with the final diagnosis of epilepsy, 55 per cent had positive tests. It may be assumed, therefore, that the potential for seizures is less in the present group than in the previous group. In the present group, one patient had a seizure after the second injection of pitressin. All others had seizures only after at least four injections of pitressin were given. One patient, an officer, had no seizure until eight hours after the tenth injection of pitressin. Two patients had hysterical seizures and a third a probable hysterical reaction.

Summary

A final diagnosis of epilepsy was made in fifty-seven cases out of a total of seventy-three suspected of epilepsy. Of these, 60 per cent gave a history of seizures prior to enlistment.

There was no apparent close relationship between the onset of seizures and combat experience, head trauma, or serious illness in this group, except for the possibility of two cases of dengue fever, following which seizures occurred. A definite family history of convulsions was elicited in 23 per cent of the patients with the final diagnosis of epilepsy. Evidence of a personality disorder or mental deficiency was found in 40 per cent of the established epileptics. Psychological tests gave evidence of appreciable maladjustment in forty-two cases of this group of fifty-seven epileptics. The significance of these findings was not determined. The electroencephalogram was definitely abnormal in only 54 per cent of the cases in which the diagnosis of epilepsy was considered justified. A comparison of this military group of established epileptics with a civilian group revealed a lower percentage of abnormal electroencephalograms in the former, which implies that the con-

USES OF RADON OINTMENT

ROBERT E. FRICKE, M.D.,
Rochester, Minnesota

SINCE the inception of roentgen and radium therapy and their widespread and effective use in treatment of cancer, ulceration due to injury to the skin has presented a serious problem. The cutaneous damage may have resulted from the repeated treatments required to destroy a malignant lesion or from some individual idiosyncracy, as the tissues of some people will not tolerate an amount of irradiation harmless to most. In either case, the radiodermatitis may not appear for some years after the exposures. It often appears as a telangiectasis which is permanent; subsequent trauma may produce a chronic ulcer. The ulceration differs from most inflammatory ulcers in that the poor blood supply, due to sclerosis of the vessels, nullifies any tendency to heal spontaneously or following the administration of stimulating ointments. This damaged vascularization also discourages attempts to excise the ulcer and graft successfully. The indolent ulcer refuses to heal and eventually a malignant lesion is prone to develop.

These indolent ulcers have presented a serious problem to radiologists and dermatologists for many years, and many ointments and medicinal preparations have had their vogue. However, these preparations fail to afford complete satisfaction. Preparations of the leaves of Aloe vera, ointments containing sulfonamide compounds, gramicidin ointments, aluminum subacetate washes, petrolatum irradiated with ultraviolet rays, and so forth, have shown some promise in the past but have not been absolutely satisfactory.

The type of therapy discussed in this study is the use of alpha particles provided by radon absorbed in petrolatum or lanolin. Alpha particle treatment was described by Fabry[1-3] in 1925 and 1926. He used thorium X in petrolatum with encouraging results. Since 1930, Uhlmann[6,7] has continued this form of treatment, employing radon in petrolatum or lanolin.

The alpha particle is the nucleus of the helium atom with two positive charges and is emitted by radium in its disintegration to form radon, and by radon in its decay to become the elements of lighter atomic weight known as the active deposit. The radiations producing the ulceration of the skin are beta rays, gamma rays and roentgen rays. The alpha particle is never used in cancer therapy. Its range is limited to a few centimeters in air and it is stopped by the thinnest glass wall or by a piece of paper. As all radium and radon used in cancer therapy are enclosed in metal, alpha particles are not utilized.

Hence, while alpha particles are a component of the irradiations given off by radium and its decay products, they had no part in producing the injury but are a formerly unused portion of the irradiations.

Preparation

In cancer therapy, radium salt or radon is utilized. After radium bromide or chloride has been dissolved in water, the gas radon is collected and purified. Radon decays rapidly; its half-value is 3.85 days. Any clinic using a radon plant for cancer therapy can readily manufacture radon ointment. The gas is absorbed readily in petrolatum or lanolin; it is sixteen times as absorbable in petrolatum as in water at room temperature. Extremely weak preparations are used; in cancer therapy 50 mg. of radium sulfate or 50 millicuries of radon are common units of treatment. Radon ointment is commonly used in the strength of 40 to 100 microcuries (0.04 to 0.1 millicurie) to the cubic centimeter or gram of petrolatum. Metal seeds containing radon are broken into a jar of petrolatum and the strength of the preparation is measured by its gamma radiation.

The range of the alpha particle is only 0.1 mm. in tissue but penetration of the petrolatum favors a deeper absorption. Experiments quoted by Low-Beer and Stone[5] indicate that radon may be absorbed even through intact skin.

Technique

The treatment of the ulceration with radon ointment usually is patterned after that suggested by Uhlmann. Radon ointment is freshly prepared in the strength of 30 to 100 microcuries per cubic

Read at the annual meeting of the American Therapeutic Society, Atlantic City, New Jersey, May 11 and 12, 1946.

centimeter of petrolatum. It is spread over the surface of the ulcer in a layer 4 to 5 mm. thick and immediately covered with a piece of rubber, oilcloth or other material, sealed in place with overlapping strips of adhesive. This is done to retard the escape of radon from the petrolatum. The ointment is left in place for eight hours and then removed. The application is made once a week for eight or ten weeks with freshly prepared ointment each time. Usually, by the end of the third application healing becomes evident. If there is no evidence of healing, a malignant lesion is probably present and the radon ointment treatment may be discontinued. It is important to know that radon ointment therapy is valueless in the face of malignant change.[7]

Williams and I[4] previously reported the experience with the first two patients treated at the Mayo Clinic with radon ointment; these were treated in 1943. These two cases provided the sternest test possible, as both chronic indolent ulcers had already undergone malignant change. Radium therapy was employed to control the cancer and radon ointment to stimulate healing of the ulcer. The first patient, a woman presenting an ulcer in the right groin, which had not healed completely for twenty-four years, obtained palliation and partial healing over the next two years, but the malignant process could not be controlled entirely. The second patient, a man, had a huge perianal ulcer of seven years' duration following roentgen treatment for pruritus ani in 1925. Biopsy from several regions showed low grade carcinoma. The cancer was arrested by radium therapy and the huge ulcer healed completely with the application of radon ointment.

Since 1943, several patients who had chronic ulcers have been treated. The ulcers treated had not undergone malignant change. Definite healing appeared in six of ten of the ulcers treated; of the four failures three appeared due to insufficient treatment, the patients neglecting to return after only one or two applications.

Other Uses

Besides chronic ulcers due to roentgen or radium irradiation, treatment with radon ointment has shown promise in two other conditions. Cavities and ulcers of the vaginal wall with foul necrotic slough, which appear in some people following radium therapy for carcinoma of the uterine cervix, seem to represent delayed healing. The tissues of these patients do not seem to react normally to radiation and do not heal in the usual manner.

These ulcers of the vaginal wall are as resistant to ordinary stimulating medications as roentgen ulcers of the skin. During the past two years, seven patients who had this condition were treated with radon ointment; four showed excellent response. The three not apparently helped abandoned treatment after one or two applications.

Another use made of radon ointment in 1945 was an attempt to stimulate epithelization following operation to construct a vagina in cases of congenital absence of that structure. Grafting of the newly formed vaginal cavity appeared hastened and even the deeper tissues appeared more flexible and resilient after radon ointment therapy than when it was not used. The surgeon performing these operations was pleased with the results and referred all his patients, following this rare operation, for postoperative treatment. The radon ointment was spread over the plastic mold used to maintain patency of the newly formed vagina. Treatments were eight hours long and were given once a week for eight or ten weeks. Twelve patients were treated in 1945 with marked benefit to all.

Conclusions

Radon absorbed in petrolatum or lanolin has so far shown promise in the treatment of chronic indolent ulcers with poor blood supply, occurring usually many years after irradiation therapy. This type of ulcer has proved exceedingly refractory to other forms of treatment. In the future these ulcers may become more common, as irradiation is pushed to its limits in combating cancer.

Radon ointment therapy is tedious, extending over several weeks' time, and is not by any means successful in every case. Some patients are not helped. If malignant change has occurred, healing will not ensue. It is important to remember that radon ointment has no effect on malignant tissue. Additional suggested uses are treatment of necrotic ulcers of the vaginal wall, which occasionally follow irradiation therapy of cancer of the uterine cervix, and to stimulate growth of granulation tissue after the operation for construction of a vagina in patients who have had a congenital absence of that structure.

CLINICAL-PATHOLOGICAL CONFERENCES

ACUTE ISOLATED MYOCARDITIS (FIEDLER'S MYOCARDITIS)

A. J. HERTZOG, M.D., and W. D. HAYFORD, M.D.

Minneapolis, Minnesota

Dr. Hayford: This case (A-46-1626) is that of a thirty-one-year-old white woman who was admitted to the Minneapolis General Hospital on August 20, 1946. She was complaining of a feeling of tightness across the chest and of a very rapid heart beat. Her past health had been good. She had had scarlet fever at some time during her youth. She was the mother of four children. There was no history of hypertension. In May of 1946, she was confined to bed for one month because of swelling of both legs. She had less severe cardiac palpitation at this time. The details of this illness are not known.

Physicial examination on admission to the hospital showed a pulse rate of 220 per minute and regular. The temperature was normal. The blood pressure was 94/80. She was a small, poorly nourished white female in no acute distress. The point of maximal impulse of the heart was found in the fifth interspace about 8 cm. to the left of the midsternal line. The tones were very forceful. There were no murmurs. The lungs were clear. The liver was not palpable. There was no evidence of congestive heart failure. The remaining examination showed nothing of note. An electrocardiogram showed a tachycardia with a rate of 220 and slurring of the ST segment in all three leads (Fig. 1). The tachycardia was thought to be supraventricular in origin. The Kline and Rytz tests were negative for syphilis. Blood chlorides were 638 mg. per cent. Urinalysis and leukocyte count were not completed, due to her short stay in the hospital.

At 3:00 A.M. on August 21, she was given 4.0 c.c. of cedilanid intravenously to begin rapid digitilization. At 9:00 A.M., she stated that she felt somewhat better althought her heart rate was still as rapid as it had been upon admission. Carotid pressure or pressure on the eyeballs did not affect the heart rate. Forced vomiting by irritating the throat and forced-held inspiration also had no effect on the heart rate. She was given a second dose of 4.0 c.c. cedilanid. A second electrocardiogram at 9:20 A.M. showed a tachycardia over 200 per minute and some ST depression. At 10:00 A.M., the patient suddenly stiffened in bed and developed a marked opisthotonus. She suddenly became cyanotic. Respirations became very slow. Artificial respiration was instituted and oxygen was given. She failed to respond and died at 10:02 A.M., on August 21, 1946.

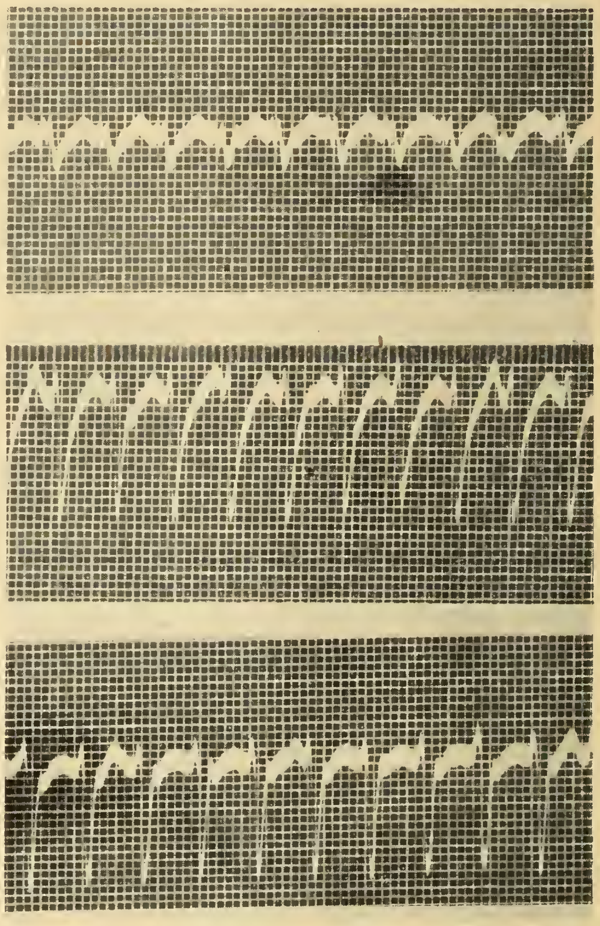

Fig. 1. Electrocardiogram showing marked tachycardia.

Dr. Donald H. Peterson: X-ray films of her chest do not contribute much. The heart appears normal in size with nothing unusual about the contours of the cardiac silhouette. The pulmonary markings are indistinct because the patient moved somewhat at the time of exposure.

Dr. Hertzog: I think we should have a discussion of this case before we give the autopsy findings. Does any one wish to ask any questions or make a diagnosis?

From the Minneapolis General Hospital, A. J. Hertzog, M.D., pathologist.

Intern: She was confined to bed in May of this year with a tachycardia and swelling of her legs. I would guess that she had acute rheumatic heart disease with an endocarditis and possibly a myocarditis.

Dr. Hayford: The story that we were able to gather from her and her family made a very poor one for rheumatic fever in May. We were not impressed.

Student: How long can a severe tachycardia persist without resulting in heart failure?

Dr. Herman Koschnitzke: In general, a tachycardia of 240 or more if continuous for five days or longer becomes incompatible with life. Such a tachycardia reduces the blood flow through the coronary arteries by reducing the diastolic interval. Systolic contractions occur so fast that the heart is not properly filled with blood during diastole. This embarrasses the coronary circulation. Coronary sclerosis in older patients further reduces the margin of safety.

Student: Why was she given digitalis instead of quinidine?

Dr. Hayford: Cedilanid was given because the tachycardia was first thought to be supraventricular in origin. Further study of the electrocardiograms showed it to be ventricular in origin. Quinidine would then be the treatment of choice.

Student: Is it possible to have a ventricular tachycardia as severe as this without the presence of organic heart disease?

Dr. Hertzog: Occasionally, it may happen. However, we always think first of an anatomical basis for the tachycardia, particularly coronary sclerosis in older people. Dr. Sether will give the autopsy findings.

Autopsy

Dr. Julian Sether: The body was that of a small poorly nourished female weighing approximately 105 pounds. There was no peripheral edema or signs of congestive heart failure. The transverse cardiac diameter was 12 cm. as compared to a transverse thoracic diameter of 24 cm. The heart weighed only 270 grams. The epicardial surfaces were smooth. The left ventricular wall measured 1 cm. in thickness. The right ventricle appeared dilated and measured 0.4 cm. in thickness. The musculature of the heart was soft and flabby. The valves and chordae tendineae were normal. The circumferences of the valves were as follows: aortic 6 cm., pulmonic 6 cm., mitral 8 cm., and tricuspid 12 cm. There was no evidence of any endocarditis. The musculature of the left ventricular wall and interventricular septum contained irregular yellowish-grey patches measuring up to 3 cm. in size. They somewhat resembled areas of fatty metamorphosis. The right lung weighed 180 grams and the left, 160 grams. They appeared crepitant and were not edematous. The liver weighed 1,240 grams and appeared normal. The spleen, kidneys, gastrointestinal tract, and remaining organs appeared normal.

Dr. Hertzog: We had to wait for the microscopic sections of the heart muscle to be sure as to what we were dealing with in this case. I will show you on the screen a section of the myocardium. There is a very severe diffuse myocarditis. The myocardium is infiltrated with large numbers of mononuclear cells, eosinophiles, and clumps of neutrophiles. There is extensive degeneration of the muscle fibers. The large multinuclear giant cells you see represent degenerating muscle fibers (Fig. 2). Nothing resembling Aschoff nodules is seen. Sections of the valves showed no evidence of any endocarditis. The epicardium appeared normal. The pathology is hence essentially a severe diffuse idiopathic myocarditis. A gram stain was negative for bacteria. Sections of the remaining organs showed nothing of note except slight patchy atelectasis of the lungs and passive congestion of the liver.

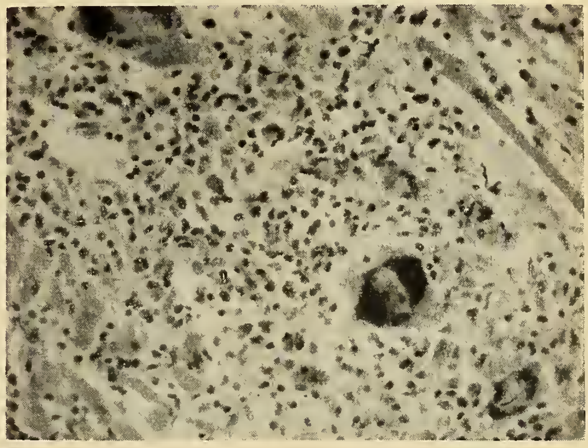

Fig. 2. Photomicrograph of myocardium showing severe diffuse inflammation and degenerating muscle fibers.

This case is then one of diffuse isolated acute myocarditis. We use the term isolated to mean that it is confined to the myocardium and there is no evidence of any disease in other parts of the heart or body. This type of heart disease is well recognized as Fiedler's myocarditis. It does not resemble a rheumatic myocarditis. However, I do not think we can completely eliminate rheumatic fever as an etiological factor from the histology. The reported cases of myocarditis due to sulfa sensitivity that I am familiar with have never shown any muscle degeneration such as one sees in this case. Furthermore we have no history of any sulfa therapy. Dr. Hayford will give us a short review of the literature of myocarditis with special reference to Fiedler's myocarditis.

Discussion

Dr. Hayford: The term, myocarditis, is one that has been badly abused. It should be limited to true inflammations of the myocardium. Many physicians in the past used the name loosely to describe myocardial exhaustion and changes in the myocardium secondary to coronary disease. It is hence difficult to evaluate the older reports on the incidence of myocarditis in autopsy material. One of the best reviews of the subject in recent years is that of Saphir.[8] Saphir classifies myocarditis as follows: fetal; specific, due to such diseases as rheumatic fever, tuberculosis, or syphilis, et cetera; myocarditis in infectious-disease with or without endocarditis; and isolated or Fiedler's myocarditis. He found 240 cases of myocarditis in 5,626 autopsies. This is an incidence of 4.26 per cent. In this series, there were fifteen cases listed as isolated or Fiedler's myocarditis. Dr. Clawson[1] found only one questionable case of the granulomatous type in his series of 6,283 hearts in the files of the pathology department of the University of Minnesota. Fiedler[4] in 1899 described the condition as follows: "There is an acute, rapidly occurring inflammation of the myocardium which most likely is due to micro-organisms. This same occurs, as a rule, in young people with or without fever. The pulse rate is markedly increased, and uncommonly decreased; the heart is dilated to the right and left; heart action is irregular; dyspnea, cyanosis, congestive phenomena in both greater and lesser circulation occur; and there is a marked tendency to cardiac weakness. The disease is localized mainly in the myocardium and causes there an interstitial myocarditis, the remaining organs being uninvolved or having only a secondary inflammation." Isolated myocarditis is commonly a disease of young people, the most common age period of reported cases being twenty to fifty years of age. The onset is often sudden, accompanied by a chill. Dyspnea, precordial distress, tachycardia, and weakness are common symptoms. Sudden death occurs frequently. A review of the literature shows that two distinct histological types have been described. One is characterized by the presence of granulomatous lesions and the other by a more diffuse type of inflammation. A form of myocarditis due to sulfonamide therapy has become well known to pathologists in the last three or four years. Such cases have been reported by Weller and French[9] and Lederer and Rosenblatt.[6] Most of these cases have been interstitial myocarditis with little or no muscle degeneration. Cases very similar to our case have been reported in the last few years by Coulter and Marcuse[2]; Mallory[7]; Hansmann and Schenken[5]; and Covey.[3] The disease known as isolated myocarditis probably has a variety of undiscovered causes.

CONGENITAL URETHRAL VALVE

A Report of Two Cases

HAROLD H. JOFFE, M.D., W. E. HATCH, M.D., and ARTHUR H. WELLS, M.D.

Duluth, Minnesota

Dr. A. H. Wells: We wish to present two cases of urinary obstruction due to congenital valves in the prostatic urethra. They illustrate some of the difficult diagnostic features of this lesion found in widely separated age groups.

Dr. R. E. Nutting: This three-and-a-half-month-old white male infant was admitted on September 13, 1946, weighing 13 pounds 10 ounces. He had been adopted by his present parents at the age of six days, at which time he was apparently normal and healthy. The mother complained that for the past three or four weeks the infant had been having noisy and heavy breathing. I found him in apparent good health on August 17, 1946. However, since that time she noticed that her child had become rather pale. His diet was changed about one month prior because of some "digestive disturbance." On September 12, 1946, the evening before admission, the child vomited once and refused all food. The following day we found a hemoglobin of 50 per cent associated with rapid, heavy respirations, enlarged heart, possible palpable spleen, and an enlarged bladder. The infant was brought to the hospital for immediate transfusion.

In the hospital, a preliminary examination revealed rapid and heavy breathing associated with expiratory rasping but no evidence of any respiratory obstruction. There was a mass in the left upper quadrant, thought to be an enlarged spleen. The heart rate was 150 per minute and regular. The hemoglobin was 9.5 grams with a red blood cell count of 3,700,000, a white blood cell count of 13,600 and a normal differential count.

During the preliminary examination while in the oxygen tent, the child had a generalized convulsion associated with involuntary passage of stool and urine. He expired approximately three hours after admission without the blood transfusion.

Dr. A. H. Wells: This fairly well developed and nourished 3½-month-old white male infant was found to have a valve like fold of mucous membrane sweeping down from the verumontanum to the left and protruding into the prostatic urethra to a sufficient degree to almost

---

From the Department of Pathology of St. Luke's Hospital, Duluth, Minnesota, Arthur H. Wells, M.D., Pathologist. Clerical assistance by Miss Faith Gugler.

completely obstruct this passageway (Fig. 1). There was a similar fold passing down from the verumontanum and swinging over to the left lateral wall. However, this structure was small in comparison and apparently played very little part in the obstruction. The prostatic urethra above the valve on the left was severely dilated and cone shaped. The urethral orifice gaped widely. The urinary bladder had severely hypertrophied and thickened walls. It contained approximately 50 c.c. of clear amber-colored fluid, and its fundus extended half way up between the symphysis pubis and the umbilicus. Its mucosal surface was rather severely trabeculated. The ureters were bilaterally severely dilated and tortuous. Both kidney pelvi had extreme dilatations, and there was severe atrophy of the parenchymal tissue of both kidneys. The kidneys weighed 30 and 32 grams respectively and measured approximately 3x3.5x6 cm. Their thin shell-like walls had no grossly normal appearing kidney tissue. The blood urea nitrogen was 214.4 mg. per cent and the creatinine 5.25 mg. per cent. Incidental findings were cardiac hypertrophy (60 grams) due primarily to hypertrophy of the left ventricle and mild dilatation of all cardiac cavities. There were toxic changes of moderate grade in the myocardium, liver, and spleen.

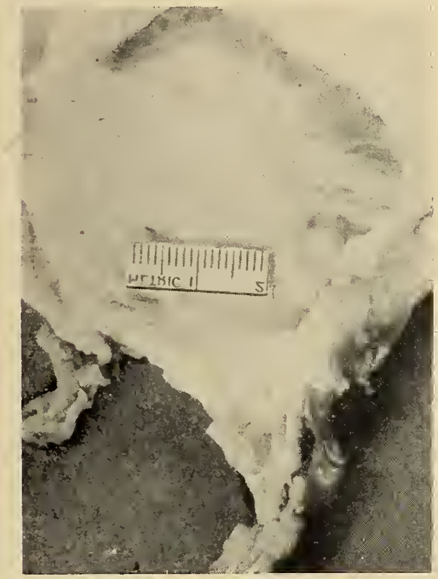

Fig. 1. Arrow points to curved shelf-like valve obstructing prostatic urethra. See dilated prostatic urethra, also dilated and trabeculated bladder.

Final diagnosis—Congenital urethral valves (a) dilatation of posterior urethra, (b) hypertrophy and dilatation of bladder, (c) bilateral hydroureter (severe), (d) bilateral hydronephrosis (severe), (e) uremia (immediate cause of death), (f) cardiac hypertrophy and dilatation of cavities, (g) toxic changes in myocardium, liver, and spleen.

Dr. W. E. Hatch: I wish to present the case of a young white man of twenty-one years who gave a history of persistent bed-wetting up until the age of sixteen, also the constant necessity of much straining with micturition and the observation of a gradual reduction in the size of an already small stream of urine. He had had a dull low backache for several years and for the past year had noticed an accentuation of this pain in the right flank. He was extremely nervous and apprehensive and had given up the idea of going to college. The effort necessary for micturition was quite noticeable. He had a residual of 60 c.c. of cloudy urine with 30 to 40 pus cells per high-power field. The urine had a normal specific gravity. There were 5,500,000 red blood cells, a hemoglobin of 17 grams, and 12,650 white blood cells.

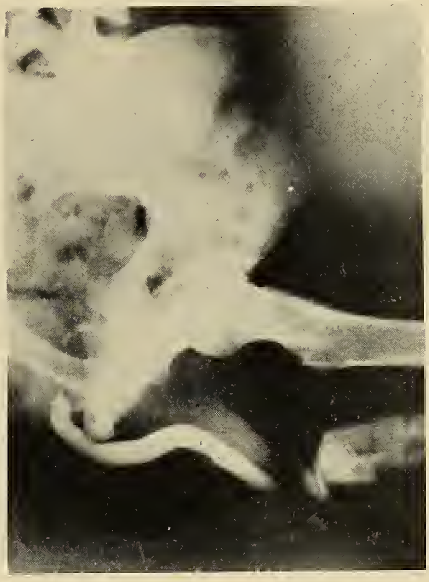

Fig. 2. Proximal urethra filled with opaque media revealing site of obstruction in posterior urethra.

The cystoscope was passed into the bladder only after overcoming considerable resistance in the posterior urethra, where much manipulation was necessary. Mild cystitis and early trabeculation was seen on the bladder mucosa. Many pus cells were found in specimens from both kidney pelvi. The pyelogram revealed a uniform moderate dilatation of the pelvis on the right side and a normal pelvis on the left. A urethrogram (Fig. 2) revealed a constriction in the posterior urethra. A thorough inspection of the urethra using the urethroscope and the McCarthy fore oblique cystoscope revealed congenital valves of the infra montanae type. There was only a mild congestion of the mucous membrane of the posterior urethra.

The congenital valves of the urethra were severed using the McCarthy resectoscope with the cutting current. An indwelling catheter with irrigation for a few days was the only postoperative treatment used.

The patient immediately noticed marked improvement in his freedom of urination. Various types of cystoscopes were passed at different times since the operation without meeting the former resistance and urethrograms failed to reveal the obstruction found in Figure 2. In six months he gained 26 pounds, his nervousness subsided, ambition and energy increased and he went to college. It is now almost ten years later and he has had no further difficulty with urination.

Discussion

Dr. H. H. Joffe: Counseller and Menville[2] reviewed eighty-four cases with congenital urethral valves and found that 75 per cent occurred before the age of ten and 52 per cent before the age of five. These figures closely parallel the age incidence of other reports.[10,14,18] The ratio of males to females is about 3:1.[15] Stevens[14] in 1936 found fourteen cases of obstruction of the female urethra by diaphragms or valves. There were approximately 130 cases reported in the literature up to 1945.[17]

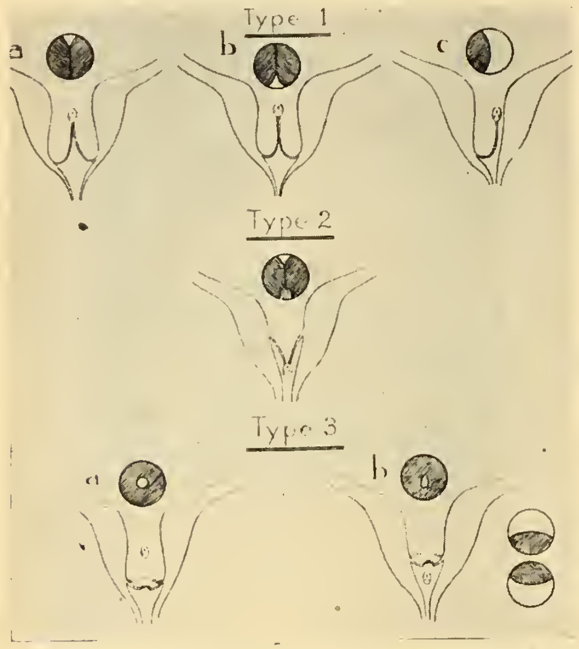

Fig. 3. Taken from Young and McKay.[18] Three types of congenital urethral obstruction.

Etiology

The early anatomists regarded the congenital valves as dilated lacunae, aberrant folds of mucosa or adherent fibrin masses.[10] At present there is no unanimity of opinion as to their formation. Many explanations of etiology have been advocated, none of which adequately explain all types of the valves. The following are some of the proposed theories:

1. Simple enlargement of normal prostatic urethral folds.[1,13]
2. Developmental anomaly of the Wolffian and Mullerian ducts.[4,6]
3. Anomalous attachment of the verumontanum to the roof of the posterior urethra.[10,13,16]
4. Persistence of the fetal urogenital membrane.[1,4,6,13]
5. Remnant arising from the fusion of the entoderm with the ectoderm.[17]

According to Watson[16] valves of the prostatic urethra may have their origin as early as the fourteenth week of fetal life and occur at the time of marked epithelial activity.

Davidsohn[3] reported a case of identical congenital valves in twins. The placenta and membranes were not properly examined, therefore the monozygotic or dizygotic nature of the twins were unknown.

Classification

The classification of Young[1,3,4,17] is the most widely accepted (Fig. 3). Here congenital valves of the posterior urethra are divided into three types, with type I being the most common.

Type I: A ridgelike fold extending distally from the verumontanum and dividing into two membranous sheets which are attached to the sides of the prostatic urethra (Fig. 3).

Type II: A similar ridge and folds as in Type I extending proximally towards the internal sphincter where they are attached to the urethra (Fig. 3).

Type III: A diaphragmatic fold, iris type, incomplete crescent or semicircular fold on either side of the urethra which may occur in any portion of the prostatic urethra with a small central or eccentric aperture (Fig. 3).

Pathological Anatomy

The results of obstruction to the flow of urine are those incident to any urethral obstruction[1] and the degree of pathology is proportional to the amount of obstruction.[17] An original hypertrophy of the bladder musculature and trigone may in time fail to overcome the resistance of the valves with a resultant dilatation and residual urine. Dilatation of the posterior urethra proximal to the valves, bilateral hydroureter and hydonephrosis usually follow with eventual death from uremia in untreated cases. The resultant urinary stasis predisposes to cystitis, ureteritis, pyelitis and pyelonephritis.

Symptoms

According to Whipple[17] over half of the 130 cases reported in the literature were not diagnosed during life, which emphasizes the fact that this entity is not as widely known as it should be. The symptoms are those produced by the local obstruction, secondary infection, and resultant uremia. The chief complaint is usually some disorder of urination such as pain, retention, incontinence, frequency, eneuresis, and dribbling. Difficulty in starting the stream and in voiding are among the early manifestations and may date back to birth.[2] Frequency even in the absence of infection is common in all except in the late stages because of the reduced elasticity and working capacity of the hypertrophied bladder.[10] Eneuresis may be the sole complaint and in a series of forty cases reviewed in the literature was reported in twenty-nine cases.[6] All were between the ages of five and fifteen. The symptoms of fretfulness, loss of weight or failure to gain weight, protuberant abdomen, secondary to a distended bladder, chills, fever, and pyuria of secondary infection and evidence of renal damage are of paramount importance. With extensive damage to the kidney, signs of renal insufficiency are manifested by low renal function, anemia, retention of nitrogenous products in the blood, gastrointestinal disturbances, such as nausea, vomiting and anorexia, also neurological symptoms, and finally lethargy and coma.[1,2,5,6,8,9,10,13,18] The fallacy that the bladder is always distended sufficiently to be seen or felt is shown in the series of Campbell[15] and Thompson.[15] A history of continuous difficulty in urination since birth is highly suggestive of congenital valvular obstruction of the posterior urethra.[13]

Diagnosis

Dr. W. E. Hatch: The following conditions should be considered in a differential diagnosis: vesical or urethral calculi, hypertrophied verumontanum, chronic pyelonephritis, congenital polycystic kidney, congenital strictures, new growths of the prostate or urethra, and cord bladder with paralysis and those associated with spina bifida.

It is of importance to keep in mind that valves while obstructing the flow of urine may offer no resistance to the passage of a sound into the bladder because the valves fall back against the side of the prostatic urethra during the passage only to return to their original obstructing position.

The most valuable diagnostic procedure is that of cystoscopy and endoscopy with a carefully prepared lateral x-ray view of the urethra filled with opaque media. There should be a characteristic dilatation of the bladder neck and posterior prostatic urethra above a constricting point. An excretory urogram may well indicate the degree of kidney and urethral damage. Bladder residual, urine cultures and blood chemical analyses help complete the study. Great care and a diminutive cystoscope are essential to the study of an infant bladder.

Treatment

Treatment is based on relief of urinary obstruction and the method of choice is transurethral resection.[1,2,11,13,15,18] There are advocates of perineal urethrotomy[11] and suprapubic[9,12] cystotomy approaches.

Special care must be exercised in handling the tiny delicate structures in infants. A slow decompression extending over two or more days is essential in the more severe cases at any age. A long period of urethral drainage of the bladder and chemotherapy may be advisable before an attempt at destroying the obstructing lesion. In cases with severe renal impairment the prognosis is poor, especially if urinary tract infection is well established.

Summary

Two cases of congenital valves obstructing the urethra have been reported. The one in a three-and-a-half-month-old infant was recognized only after it had led to death through uremia. The second patient, a twenty-one-year-old man, had congenital prostatic urethral valves which proved the basis of sixteen years of bed-wetting. He also noticed increasing difficulty with urination, small urinary stream, low backache, pain in the right flank, and psychologic disturbances. He was completely cured following transurethral resection of the valves.

A brief review of the literature concerning the etiology, classification, pathological anatomy, symptoms, diagnosis and treatment are included.

Uses of Radon Ointment

(Continued from Page 53)

While the true value of radon ointment is not known and work with it is still experimental, sufficient promise has been shown to encourage continuance of this form of therapy.

CASE REPORT

UNUSUALLY LARGE OVARIAN CYST IN AN ELDERLY WOMAN

LYMAN B. CLAY, M.D. and VERNE S. CABOT, M.D., F.A.C.S.
Minneapolis, Minnesota

THE unusual size of the tumor, age of the patient, and the prolonged history are features which make this case of interest to the surgeon.

The patient, a white woman, was first seen by us when she was sixty-eight years of age. Her complaints were vertigo, fainting, and indefinite gastric distress. On physical examination she was found to have a moderate hypertention, and her abdomen was symmetrically distended and flat to percussion. The uterus was pushed down deeply into the pelvis, and both vaginal vaults were shortened and tense to palpation. A diagnosis was made of a cystic tumor arising in the pelvis and extending as high as the xiphoid process. The patient gave a history of having been examined fifteen years previously and told that she had an ovarian cyst about the size of a grapefruit. Since that time her abdomen had steadily enlarged, although her extremities and face became progressively thinner. No treatment had been instituted.

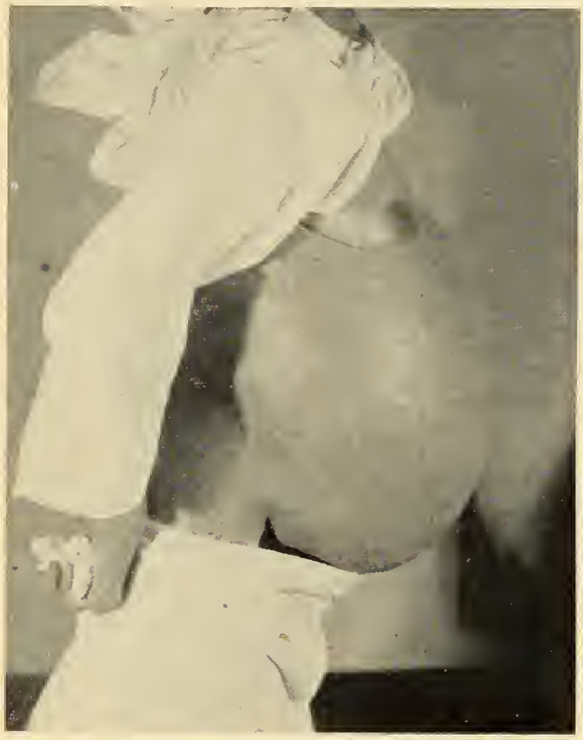

Fig. 1. Abdominal distention with patient erect.

We advised hospitalization but this was refused. She was, therefore, treated symptomatically at home. During the next three years the distention continued to increase and her symptoms became more severe. She developed a partial obstruction of the bowel, accompanied by pain, and finally consented to be hospitalized.

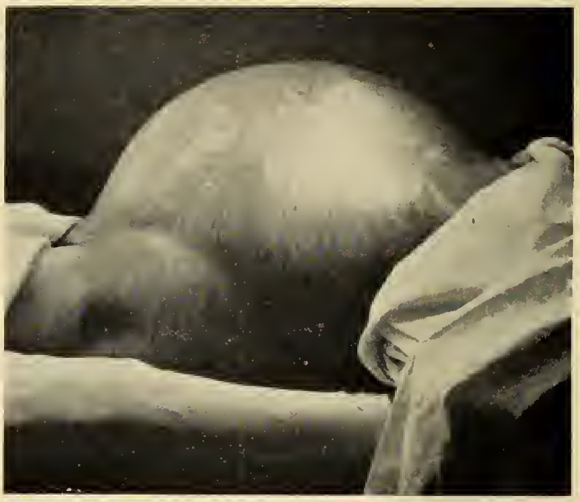

Fig. 2. Abdominal distention with patient lying down.

After a few days of preparatory treatment, the abdomen was opened under local anesthesia supplemented by nitrous oxide. A large cystic tumor was encountered filling the entire abdominal cavity from the pelvis to the diaphragm. The bowel was compressed and pushed into the lateral gutters. The tumor was tense and thick walled. A trochar was inserted and a large quantity of clear straw-colored fluid evacuated. There were multiple locules, many of which had to be drained before delivery of the cyst from the abdomen could be accomplished. A large pedicle attached to the right broad ligament was easily ligated and amputated. Immediately after closure of the abdomen, a large turkish towel was folded and strapped tightly over the dressing to compress the abdomen. The four extremities were wrapped with elastic bandages. Although she vomited some bloody fluid the first day, these measures proved successful in preventing a marked fall in blood pressure and the patient's convalescence was quite uneventful. She was discharged on the twenty-third hospital day.

The cyst, when refilled with water, weighed 42 pounds but due to the many small locules could not be distended to its full capacity. The pathological report was, "a multilocular cyst lined with a single layer of columnar epithelium. There is no evidence of gross or microscopic malignancy."

After two and a half months of freedom from symptoms, the patient again became suddenly ill with fever and vomiting. At this time she showed a weight gain of thirty-five pounds since her discharge from the hospital. Her symptoms subsided, but in a few days they recurred, accompanied by rapid abdominal distention, marked pyuria, and albuminuria. Gastrointestinal studies were negative except for a small herniation of the stomach into the esophageal hiatus of the diaphragm. A paracentesis was performed and nine liters of amber fluid obtained. The centrifuged specimen showed metastatic carcinoma cells.

One month later there was a return of the ascites, and we elected to do an exploratory laparotomy. A large amount of straw colored fluid was found, and the omentum and abdominal organs were studded with metastatic carcinomatous lesions.

Following operation, the patient failed rapidly and expired on the fourth postoperative day. The post-mortem findings were:

1. Metastatic carcinoma involving the serous surfaces of the abdominal organs and omentum.
2. Coronary sclerosis grade 4.
3. Pulmonary edema.
4. Thrombosis of the abdominal aorta and vena cava.
5. Fatty metamorphosis of the liver without carcinomatous involvement.
6. Cholelithiasis.

It was the pathologist's opinion that the primary lesion was probably small and passed unobserved in the original cyst, as none could be found at post-mortem examination.

Observations on a Mild Form of Epilepsy

(Continued from Page 51)

vulsive states of the military group were of a milder character. Grand mal convulsions were induced with the water-pitressin test in 23 per cent of those with the final diagnosis of epilepsy. This is less than one-half the percentage of positive tests in a previous group which also suggests a less severe grade of epilepsy in the present group.

Rectal Impalement

(Continued from Page 46)

Discussion

The wisdom of closing the rectal tear in the primary operation might be questioned. This was done, however, to prevent extrusion of a loop of small gut; allowance was made for drainage into the rectum from the contaminated area. That this was adequate is evident from the prompt formation of a rectovesical fistula without apparent urinary diffusion into the perivesical tissues.

The triple nature of this injury merits some comment regarding anatomical variation of the rectovesical pouch of Douglas. Obviously, only a rather deep one would make it possible for the impaling agent to penetrate in a straight line, the rectum, peritoneal cavity and bladder, and such was found to be the case at operation.

NOTES ON THE HISTORY OF MEDICINE IN FILLMORE COUNTY PRIOR TO 1900

By NORA H. GUTHREY
Mayo Clinic
Rochester, Minnesota

(Continued from December issue)

Henry C. Grover, of Irish descent, was born to American parents on March 26, 1830, on a farm in Union County, Indiana. His father, Josiah Grover, who successively was saddler, farmer and storekeeper, was a native of Kentucky; his mother was Sophia Everts Grover, daughter of Dr. Sylvanus Everts, of Indiana, originally of Vermont. Sophia Everts, as has been told, had six brothers, all of whom became physicians, so that it is not strange that of her six sons one should enter the medical profession. Of her sons, S. E. Grover and Daniel P. Grover made their homes in La Porte, Indiana; B. A. Grover lived in Missouri and S. K. Grover in Capolis, Washington. Oscar was killed in the Battle before Atlanta, Georgia, during the Civil War.

Henry Grover received his elementary education in the schools near his father's farm and he considered himself fortunate if he could attend classes three months in the year. At the age of sixteen, he left the farm to become the office boy of his grandfather, Dr. Sylvanus Everts; and predisposed as he was to study medicine, the months spent in a medical atmosphere fixed his determination to become a physician. In 1853 and 1854 he was a student at the Medical School of the University of Michigan; late in his course he transferred to the Medical School of the University of Keokuk (Iowa), of which his uncle, Dr. Orpheus Everts, was a trustee, and there he received his degree in medicine on February 22, 1855. In this same period a second uncle, Thomas Haywood Everts, likewise a student of medicine at the University of Michigan, also transferred to Keokuk, as has been told, and was graduated in 1855.

Dr. Grover's first period of medical practice, in Lake County, in northern Indiana, was terminated by the Civil War. When hostilities were declared, he enlisted as a private in the Twentieth Regiment of Indiana Volunteer Infantry and was mustered in at Lafayette, Indiana, on July 22, 1861. Six months later, on January 13, 1862, he was appointed assistant surgeon, and for the next three years he met the fortunes of war with his regiment, which not only helped to put down the Draft Riots of the week of July 13 to 16, 1863, in New York City, but was in twenty-two engagements, some of the hardest fought of the campaigns, among them the battle of Chickahominy, Hampden Roads, the Seven Days' Battle before Richmond, Chancellorsville, Gettysburg, Spotsylvania Court House, Petersburg and Appomatox Court House. Dr. Grover was continually at the front, ministering to the sick and wounded, and alleviating suffering; the gratitude and blessings of those whom he helped remained always one of his treasured memories. The kit of surgical instruments which he used in his military service he long afterward gave to Dr. R. V. Williams, of Rushford, and Dr. Williams in turn, on September 16, 1941, when he was host to friends and colleagues in the Olmsted-Houston-Fillmore-Dodge County Medical Society at a farewell dinner on his retirement from practice, presented the kit to the Mayo Clinic; it has been preserved in the medical teaching museum of the Clinic and the Mayo Foundation with other matters of interest pertaining to medical and surgical practice.

In 1864, on the expiration of his army service, Dr. Grover re-entered the Medical School of the University of Michigan for an additional year of study before returning to medical practice in Lake County. Early in 1869 he left Indiana for Minnesota, because of the excellent professional and financial opportunity that the community of Rushford, Fillmore County, afforded; his license to practice in the county was recorded on January 8 of that year. In Rushford he lived his long and useful life as a general practitioner, high in the esteem of his fellow citizens. For five years, from 1874 to 1880, he was in partnership with his uncle, Dr. Thomas H. Everts, who had settled in Rushford in 1866, an association which was broken only when Dr. Everts removed to Colorado to enter another profession.

Dr. Grover's personal worth and ability were recognized in appointments to various offices, civic and professional. He was mayor of Rushford and a member of the village council, each for three years. As a councilman he was instrumental in securing high license and in limiting the number of saloons in the village. Twice he was sent as representative of his district to the state legislature, between 1875 and 1877 and in 1879, and in his capacity as legislator he was a faithful worker for measures that would advance the effectiveness of medical practice.

In his professional capacity he served as chairman of the local board of health, as county physician, and as county coroner, first from January 8, 1873, to January 8, 1880, and in a later term from 1891 to 1892. It happened that during his first period of service as coroner, the discovery of the remains of two human bodies in a box which was anchored in a branch of the Brook Kedron, in Sumner Township, caused horrified excitement, and Dr. Grover of course was summoned. Fortunately, it proved that foul murder had not been done; the cadavers had been placed in the brook by an enthusiastic medical student to macerate that he might with a minimum of effort secure the skeletons for study.

From the beginning an exponent of medical organization, Dr. Grover was one of the early members of the Fillmore County Medical Society and he was serving as its vice president in 1879 when the society suspended activity, the officers to hold over to a more prosperous era. He was a member of the Winona County Medical Society also and when, in 1904, the Houston-Fillmore County Medical Society was formed, Dr. Grover, then seventy-four years old, became an honorary member at the insistence of his younger colleagues that his name appear on the roster. The proposal for membership was presented by Dr. De Costa Rhines, to whom, as to many others of his juniors in the profession, Dr. Grover was a kind and wise friend. A devoted friendship held in common was that of Dr. Grover and his fellow townsmen, Dr. J. W. Magelssen and Dr. H. W. Eldred, the well-known surgeon-dentist; these were a trio who by their loyalty to each other and by their humor and spontaneous wit delighted their friends and acquaintances.

In 1871 Dr. Grover became a member of the young Minnesota State Medical Society, and thereafter for many years he was active in its work. He and Dr. Everts, among the few physicians in Fillmore County who responded to requests from the organization, contributed valuable notes and reports for its transactions and both men served on various of its committees. Dr. Grover was at different times a member of the executive committee and of the groups considering medical jurisprudence, obstetrics and necrology. On November 14, 1883, under the law passed that year to regulate medical practice in the state, he received certificate No. 328 (R).

Dr. Grover did not use tobacco, was an enemy of alcoholic beverages. Although he was stern and straightforward in dealing with serious problems, he rarely expressed anger; he was kind and humorous, was fond of good stories and a contributor of many. He was a Mason and a member and supporter of the Unitarian Church. His absolute dependability and his zeal in promoting any enterprise that was for the good of his fellow men come first to the minds of those who knew him best.

Henry C. Grover was married to Sarah Jane Pratt, a school teacher who was born at Jamestown, New York. Dr. and Mrs. Grover had two children, Lucy, who died in childhood, and Fred H. Grover, a farmer, who by 1941 had retired and was living in Rushford. Dr. Grover, at the time of his death, from carcinoma, on July 4, 1910, was making his home with his son.

Thomas Edmund Hall, the son of Mr. and Mrs. Thomas Hall, among the earliest settlers of Fillmore County, was born at Preston in 1854 and spent all of his life, with the exception of the years when he was absent for study, within a hundred miles of his birthplace. Immediately after his graduation from Rush Medical College, in 1875, he began the practice of his profession in the village of Lanesboro. Although he remained only a short time then, he later spent many years there, and it is in that community that he has been remembered most clearly, perhaps especially for his keen interest in history and for his remarkable memory. One pioneer citizen of Lanesboro has been quoted as saying that Dr. Hall knew more about the Civil War than the men who fought in it; that he could read anything and recite it word for word the next minute. Another person, a veteran of the Civil War who had spent eighteen months in Libby Prison, was astonished to hear Dr. Hall, who had never seen the place, describe the exact spot where the veteran had been confined and the conditions that had existed in the prison.

Dr. Hall is said to have practiced medicine in several counties and many different towns in southern Minnesota and, although the order and exact time are not certain, trace has been discovered of various changes of residence. In 1875, in Fillmore County, he left Lanesboro for Preston and in the same year went from Preston to Brownsdale and Austin, both in Mower County. Shortly afterward he was for a time in Granada, Martin County, and not long after that was in Lake City, Wabasha County, and in Frontenac, Goodhue County. From 1878 into 1882 he was again in his native town of Preston and was co-operating actively with the Minnesota State Medical Society in obtaining data on the incidence and severity of diphtheria in Fillmore County. From Preston he moved in the summer of 1882 to Dresbach, Winona County. In the next period of three years, there were notes in the Preston newspapers about his activities and his practice and about visits to Preston by Dr. and Mrs. Hall and their little daughter. Then, in the summer of 1883 Mr. and Mrs. Thomas Hall, oldest citizens of Preston, moved permanently to Wilmington, Delaware. In this same period, under the act of 1883 to regulate medical practice. Dr. Hall received state certificate No. 781 (R).

Early in 1886 Dr. Hall settled once more in Lanesboro and through the nineties and into the new century he was listed in medical directories as practicing in that village. By 1909 he was in La Crescent, Houston County, and in the following year he crossed the Mississippi River to practice medicine and to make his home in La Crosse, Wisconsin. In La Crosse, on May 5, 1912, he died at the age of fifty-eight years. In 1941 his widow, Mrs. Rubie T. Hall, continued to live in La Crosse.

Florence John Halloran, born on October 3, 1859, at Chatfield, Minnesota, a village of both Fillmore and Olmsted Counties, was the son of Timothy Halloran and Catherine McGuire Halloran.

Timothy Halloran was one of the notable pioneer settlers of the two counties. He was the son of an Irish civil engineer, Florence Halloran, and was born near Bandon, County Cork, Ireland, on December 5, 1832. When he was twenty years old, he came to America, and after working for two and a half years in Massachusetts and for some months in Wisconsin, as he traveled west, he reached his goal of southern Minnesota in 1855 and at once pre-empted some land in Pleasant Valley, Mower County. Very soon, however, he transferred these acres to his brother, who had accompanied him, and returned to Chatfield, through which he had passed en route to Pleasant Valley. He lived in the village of Chatfield for five years and spent the remainder of his life on farms which he owned in Elmira Township in Olmsted County. In 1858 he was married to Catherine McGuire, of Chatfield, also a native of Ireland, who had come with her parents in the early fifties to southern Minnesota. By unflagging hard work, the young couple overcame the hardships and financial stress of pioneer life and won through to comfortable prosperity. Their children, like themselves, were good citizens: Michael D., a lawyer in Rochester, Minnesota, for many years until his death; Timothy, also deceased, of Duluth; Nora (Mrs. John R. Manahan), of Chatfield, and Florence John, for forty-seven years a practicing physician. In 1897 Timothy Halloran, senior, wrote from memory his *History of Chatfield,* often mentioned in these pages.

Florence John Halloran received his early education in the public schools of Chatfield and his premedical training at the Campion Jesuit High School at Prairie du Chien, Wisconsin. After his graduation from that school, in 1884, he taught school for a time before beginning his course at Rush Medical College; the *Chatfield Democrat* of October 3, 1885, stated that Florence Halloran, "for the past two years a medical student under Dr. M. A. Trow," had left that week for "a course of lectures at Rush Medical." On February 21, 1888, he took his degree of doctor of medicine from Rush and shortly afterward began his medical career in Forman, Sargent County, Dakota Territory (North Dakota), where he practiced for about a year before settling in Chatfield. In the same year he was married to Nellie Tracy, a school teacher, daughter of Mr. and Mrs. J. Tracy, highly respected pioneer settlers of Laird, Eyota Township, Olmsted County. Dr. and Mrs. Halloran had one son, Walter H. Halloran, who became a physician.

From 1903 to 1912, Dr. Halloran practiced medicine in Saint Paul, devoting himself to the treatment of diseases of the heart and the stomach. During this period, he became a member of the Ramsey County Medical Society and was on the staffs of the Lutheran Hospital and the Bethesda Hospital.

With the exception of a short period in Winona in the autumn of 1894 and the years in Dakota and Saint Paul, Dr. Halloran spent his entire professional life in Chatfield as a general practitioner. Tall and large, of fine appearance, kind, genial and witty and, moreover, a competent physician and skilled diagnostician, an omnivorous reader of the medical literature, Dr. Halloran played an important part in the life of the village and the community. He had an extensive practice, served as local health officer, as medical examiner for the local draft board in World War I, and for many years as mayor of Chatfield. He was enrolled in the local county medical society, the Southern Minnesota Medical Association, the Minnesota State Medical Association and the American Medical Association; he was a member of the Knights of Columbus and a faithful and active member of the Catholic Church. In the years prior to 1900, his chief medical contemporaries in Chatfield were John C. Dickson, Charles McH. Cooper, Aaron M. Stephens and Milton A. Trow.

That Dr. Halloran was a strong and vivid personality is clear. Recollections of his kindly wit and especially of his generosity to the sick poor are many. If fault or foible is mentioned, it is with affectionate tolerance.

In the last years of his life Dr. Halloran spent part of his time in Jackson, Minnesota, with his son, Dr. Walter H. Halloran, who owns and operates the Halloran Hospital, and after the death of Mrs. Halloran, on August 17, 1934, he moved permanently to Jackson. He died at the home of his son on January 23, 1935.

In paying final tribute to Dr. Halloran, the editor of the *Jackson County Pilot* wrote of him as one of the oldest and most prominent practicing physicians in southern Minnesota, loved by all with whom he came in contact, both for his skill and for the "pleasing geniality which always pervaded any company that he entered." And to this comment is added that of the son, who described his father as "a general practitioner of the old school, who kept abreast of the times and gave his services freely and willingly to his people, regardless of personal agrandizement."

"**Dr. Hammer,**" announced the *Chatfield Democrat* on November 3, 1883, "will sell his stock and farming implements at public auction on November 15, at his old place near Pilot Mound." This is the only mention of this practitioner in Fillmore County that the writer has seen.

Possibly the same man, a Dr. Amos G. Hammer, graduate of the Physio-Eclectic Medical College in 1867, was listed in the official state register of physicians of 1883-1890 as a resident of Redwood Falls, Redwood County, and the possessor of state certificate No. 297 (E) dated on November 10, 1883.

"**Hammond, Thos.**" was listed among the patrons of an illustrated historical atlas of Minnesota of 1874 as a physician and surgeon of section 31, Elmira Township, Olmsted County, post office Chatfield, a native of Adams County, Pennsylvania, who came to Minnesota in 1864. There is reason to believe that this was the Dr. H. Thomas who lived in Chatfield for about fifteen years and actively practiced medicine there into the eighties. A few notes on Dr. Thomas follow in alphabetic place in the present series of sketches.

Henry Howard Haskin (a final "s" was added subsequently to the surname) was born at Middlesex, Vermont, on September 10, 1844, and was one of the five children of Samuel Haskin and Polly Almira Haskin. His brothers and sisters were George, Dustin, Emmaline and Lois. Dustin died in infancy. Of the others, in later years George lived in Cushing, Oklahoma; Emmaline (Mrs. Blandin), in Minneapolis, Minnesota; and Lois (Mrs. Webster Hills) in Downers Grove, Illinois. The father, Samuel Haskin, who claimed direct descent from a passenger on the Mayflower, was a farmer and miller.

When Henry was seven years old, his parents moved west with their family to a homestead near Prairie du Sac, Columbia County, Wisconsin. There the boy grew up, attending the rural school until at the beginning of the Civil War he volunteered for service in the Union Army and was accepted. For a short time he was a fifer, but when it was discovered that he wrote a clear, legible hand he was chosen as clerk to the post adjutant at Benton Barracks, St. Louis, Missouri, and in this office he remained until he received his honorable discharge in 1865.

About three years later the Haskin family moved into southern Minnesota and settled near Granger, in Bristol Township, Fillmore County, near the Iowa line. In the winter of 1868 and 1869, Henry Haskin taught school in the village of Harmony, in the bordering township of that name on the east, and for the next three years he traveled for the Winneshiek Paper Mill Company.

On October 10, 1873, Henry Howard Haskin was married to Mary W. Adams, a school teacher of English descent, who was a native of Brandon, Vermont. To them were born two children, Leon Leroy and Ethel Leona. At this period of his life Mr. Haskin was studying law in the office of an attorney, a pursuit which he discontinued after a few months to undertake the study of medicine at the Medical School of the University of Iowa, from which he was graduated on March 7, 1877, as a doctor of medicine.

Dr. Haskin at once began to follow his profession at Kendalville, Iowa, but soon moved to Elliota, Minnesota, which was three miles from the present village, then nonexistent, of Canton. When Elliota became one of the disappointed villages of the county by reason of being left to one side by the railroad, the commercial and professional interests were moved to Boomer, which later received the name of Canton. It probably was early in his years as a physician that Dr. Haskin added or, rather, accepted a final "s" on his surname and became Dr. Haskins. As he said, everybody else put the "s" on and therefore he did also.

In Canton from 1878 for the ensuing twenty-four years, Dr. Haskins was a general practitioner of medicine and surgery and, on occasion, dentistry. A trained pharmacist as well, he owned and operated one of the two drugstores of the village; Dr. Robert A. Sturgeon, a pioneer physician in the county since 1865, who also had removed from Elliota to Canton, owned the second. Dr. Haskins enlarged his interests by conducting with S. Manual, a general store across the street from his drugstore. During these busy years Dr. Haskins served his community well, kept abreast of advances in his profession, reading the literature, taking postgraduate work at Northwestern University and joining in the work of medical associations, among them the local county medical society, the Southern Minnesota Medical Association and the Minnesota Valley Society (the latter two groups merged in 1911, taking the name "The Southern Minnesota Medical Association"), and the

Minnesota State Medical Society. On October 11, 1883, under the new Medical Practice Act, Dr. Haskins received state certificate No. 50 (R). From January 4, 1887, to January 6, 1889, he served as county coroner.

In the years from 1878 to 1887, Dr. James M. Wheat, of Lenora, in Canton Township, one of the county's earliest and most able pioneer physicians, frequently called Dr. Haskins in consultation, and in a published report of a "case of intrauterine fibroid tumor and operation" which he made to the Committee on Gynecology of the State Medical Society credited Dr. Haskins with assistance in carrying out the surgical procedure. Dr. Wheat moved to California in 1887.

As a country physician with a heavy practice, Dr. Haskins had varied experiences, some amusing, some touching or hazardous, all interesting. His daughter, Ethel Haskins Gifford, has recalled the frequent sight, early in the morning, of her father's begrimed buggy, each spoke and hub laden with mud, silent witness to the long tiresome trips in the rain and darkness. A lantern on the dashboard was the only light; side curtains and a rainproof lap cover were the only protection against the weather. Sometimes the doctor used his two-wheeled, spring-equipped cart and then was accompanied by his shaggy little black and white dog Trax, who sat beside him, watching the road eagerly. . . . One morning at three o'clock Dr. Haskins was called on to perform an emergency operation, for strangulated hernia, on a citizen of Canton; the procedure was carried out successfully, the patient on the dining-room table, in the light of an oil lamp which was held by his brother; the patient made a good recovery and lived for forty years. Another time, Dr. Haskins filled a tooth for the brother, melting a gold coin and pouring the molten metal into the cavity. The patient withstood the operation without benefit of anesthesia and carried the filling with him to his grave when he died in his eighties. . . . A favorite story was that of the little Norwegian boy who walked in from the country to have his tonsils removed, replying to the astonished physician's question that he had come alone; and after the operation he walked home alone, "a true Nordic scout."

Possessor of a brilliant mind and a keen wit, Dr. Haskins enjoyed lively arguments, in which he was not always even-tempered. His pet diversions were chess and checkers, and he took great satisfaction in having won high score in the checkers club to which he belonged. The trophy, a belt which the winner retained until defeated, was too tight for Dr. Haskins, who was inclined to portliness, and he accordingly carried it in his pocket and proudly displayed it on request. Persistency in any task he set himself was an outstanding characteristic that is recalled by old friends; he taught himself the Norwegian language and he learned to ride a bicycle, in spite of memorable mishaps.

Mrs. Haskins was an accomplished woman, intelligent and public-spirited. She was active in organizing the Women's Christian Temperance Union in Canton and in securing free textbooks for the schools—bold undertakings, unbecoming a woman it was thought by the scandalized older women of the community, who nevertheless greatly admired Mrs. Haskins. One woman, who had heard Mrs. Potter Palmer speak as hostess at the Chicago World's Fair in 1893, said that she much preferred to hear Mary Haskins.

Although he was not a member, Dr. Haskins attended the Presbyterian Church of Canton and sang in the choir. Later in his life he became much interested in spiritualistic associations. He was a Mason, member of the local Blue Lodge, of which he was several times Worshipful Master; of the Royal Arch Masons and the Order of the Eastern Star.

On Christmas night, 1899, Dr. Haskins' drug store burned; it was not rebuilt and, in 1902, retiring from medical practice, the doctor left Canton for Perth, North Dakota, where with his son he engaged in farming and in operating a general store. In 1919, having previously spent several winters in Florida, he moved permanently to that state, to Southern Cassadaga Camp, where he spent the remainder of his life. He died from influenza, complicated by uremia, on May 9, 1922, survived by his wife, Mary W. Haskins; his son, Leon Leroy Haskins, of Warren, Minnesota; his daughter, Ethel Haskins (Mrs. E. B.) Gifford, of De Land, Florida; his sister, Lois Haskins (Mrs. Webster) Hills, of Downers Grove, Illinois; and his brother, George Haskins, of Cushing, Oklahoma. Of this group, all were living in 1943 except Mrs. Haskins and George Haskins.

William Haslam was a homeopathic physician, apparently in good standing among his colleagues in homeopathic associations, who settled in Chatfield in 1869. According to Halloran's history of Chatfield, Dr. Haslam opened a drug store in the village in partnership with W. R. Edward; mention was made of Mr. Edward selling the store to John S. Gove and Mr. Gove to J. A. Ross, but further comment on Dr. Haslam was lacking. Only one other note has appeared, and that in the *Rochester Post* of October 4, 1878: "Dr. Haslam, an old philosopher well remembered in Chatfield, used to have one weather sign that he regarded as never failing, to wit: That the direction from which the wind blew when the sun was crossing the equator indicated the direction from which it would prevail for the next six months. . . ."

President's Letter

PHYSICIANS OF TODAY REJECT "PEACEFUL MEDIOCRITY" OF PAST

IN past years, an immense majority of physicians remained intellectually in a middle state. They were not inefficient, but neither did they attempt to carry their activities beyond acceptable performance of their duties as practitioners of medicine. They were content to amble on in peaceful mediocrity, adopting with little concern the current opinions of the day. They merely maintained themselves on a level with their generation and conformed to the standards of knowledge common to the age and the country in which they dwelt.

The physician of today is not like that. He knows that a passive attitude will not be effective under present conditions. He knows that he must not limit his thought and activities to purely professional duties. He knows that the welfare of the people, his patients, is menaced by zealots who are so little conscious of their deficiencies that not only are they willing to attempt impossible tasks, but they actually believe they are capable of accomplishing those tasks. He realizes that these men, perched on their imaginary eminence, have become so inflated by their fancied superiority that they attempt to teach and to manage that which they themselves do not comprehend. He knows that those who are prey to such delusions, if they also acquire the power to enforce them, will accomplish far more evil than good.

He is willing to tolerate temporary schemes which have been considered necessary in a confused period of the world's history. He has co-operated in the advancement of such activities and is willing to continue to do so in spite of inconvenience and injustice to him. He knows why these deficiencies exist. The hospital problem, the nursing problem, the office and housing problem (probably he is a former medical officer returned to civil life), the EMIC* problem and the bluebook, the prepayment insurance program, the service plan, the indemnity plan, the situation regarding hospitals and certification, the specialty boards, the Rich report and the reorganization of the American Medical Association, the meeting in Two Harbors, Jim Murray, Bob Wagner, John Dingell, Claude Pepper—yes, all of these obstructing problems, conditions and individuals, and more, are understood by him. And he complains. That is a prerogative of the citizen in a free society. Had his forebears not possessed this characteristic, probably the Declaration of Independence never would have been written. Certainly he complains. He gets together with a group of general practitioners and they speak their minds. He organizes the American College of Physicians and Surgeons in an attempt to "do something about it."

Despite unfavorable conditions that surround him, he performs his task sedulously. He understands that for him to be possessed of knowledge concerning how to fulfill his duties allows him to meet the intellectual obligations of his task and that if he is determined to do these duties in spite of all inhibitors, he will meet the moral obligations of it. He understands that these are the two most important items in his armamentarium and that only if he maintains them at peak efficiency and in harmonious relationship can he hope to contribute to the objectives of his profession. He realizes that the success or failure of American medicine rests squarely on his shoulders. He knows that the security and durability of the organization of which he is a part depend on him.

Consequently, as I assume my new duties, I feel neither uncertainty nor uneasiness. Members of the Minnesota State Medical Association are well informed. The central office of the Association is efficient. Together we can combat any man-made threats against the public health.

MINNESOTA MEDICAL SERVICE

A DETAILED report of the meeting of the House of Delegates of the Minnesota State Medical Association, held in Saint Paul on December 22, 1946, to take action on the report of its Committee on Minnesota Medical Service, appears in the section on Medical Economics in this issue.

Although the last legislature passed an enabling act authorizing the organized profession of the state to establish a nonprofit medical service to meet the need of insurance coverage for medical fees, Minnesota Medical Service has not as yet been incorporated. It is not surprising that in such an involved project, progress has been slow.

The committee and its subcommittees have had a multitude of meetings and have given much thought to the subject. The findings were submitted to the House of Delegates at its December 22 meeting. The committee submitted two contracts—one providing for surgical benefits alone and the other for combined medical and surgical benefits—and the rates which would be required. Dr. Adson, chairman of the committee, then brought out the fact that commercial insurance companies now have available indemnity policies providing benefits equal to and, in some instances, greater than those proposed by Minnesota Medical Service, at considerably less cost. The established insurance companies with 3,000 agencies throughout the state are potential handlers of these medical policies and can obviously undersell a small organization. Insurance of any kind does not sell itself, and the cost of selling is a large item in the insurance business.

It is not generally known that medical insurance policies, providing benefits identical with those proposed for Minnesota Medical Service, are already being offered and sold by the commercial insurance companies, for both groups and individuals, at a very reasonable cost.

It was felt by the House of Delegates that physicians should do everything in their power to promote the sale of these medical insurance policies offered by the commercial companies. The House approved the appointment of a committee of five physicians to publicize the availability of such policies and to give the approval of the Minnesota State Medical Association to worthy policies.

The House of Delegates, notwithstanding developments, decided to proceed with the incorporation of Minnesota Medical Service. Under its plan, indemnity policies are sold to any wage earner irrespective of his or her income. The policyholder pays the difference when the physician's fee is greater than that allowed by the policy. The policy of the Minnesota Medical Service, however, will provide for fees applicable to individuals earning $1,200 or less a year and to married persons earning $2,000 or less, and will provide complete coverage of physicians' fees for this group, which today is a small one.

Insurance against hospital costs and physicians' fees is the answer to the unequal cost of sickness, and physicians can render their patients a real service by urging them to take advantage of these policies. A list of commercial policies approved by the Minnesota State Medical Association will doubtless be forthcoming in the near future.

MORTALITY IN DIABETES

THE incongruous fact that the mortality in diabetes has been higher since insulin was discovered has been generally known. The explanation is made clear in a recent *Bulletin of the Metropolitan Life Insurance Company.*†

There are today twice as many known diabetics as there were twenty-five years ago when insulin was discovered. This probably means an actual increase in the disease itself, although the greatly increased number of physical examinations that include urinalyses undoubtedly accounts largely for this fact. The rise in the percentage of the population in the older age groups, a time when diabetes is most likely to make its apparance, also accounts for the increase in the disease.

---

† A Quarter Century of Insulin. Bull. Metropolitan Life Insurance Company, 27:8, (Oct.) 1946.

Of course, it is well known that insulin has resulted in a marked reduction in mortality among diabetics, especially among those in the younger age group. While it has resulted in a prolongation of life, diabetics can hardly live forever, and the marked increase in deaths in diabetics over the age of fifty-five is the reason for the rise in the total mortality. As a matter of fact, the death rate among diabetics, according to the article mentioned, has been markedly reduced in each decade up to the age of fifty-five. An increase is slightly apparent in men in the decade from fifty-five to sixty-four, is more evident in women in this age group, and then, in the decade from sixty-five to seventy-four, the mortality becomes more than double that of the preceding decade in both men and women.

The survey mentioned covers only the general mortality among diabetics. What role the diabetes played as a cause of death doubtless cannot be accurately determined—that is, how many died *with* diabetes and how many died *from* the disease. However, the analysis indicates, rather than detracts from, the great value of insulin in the treatment of diabetes.

HEART DISEASE

The Metropolitan Life Insurance Company, in cooperation with the American Heart Society, is conducting an educational campaign on heart care. The purpose of the campaign is to prevent heart disease and to help people with heart disease to live longer and more useful lives.

During the campaign, one and one-half million booklets entitled "Your Heart" will be distributed to the laity, and a packet containing statistical information will be sent to 43,000 physicians. Other means, such as newspapers, radio, health departments and certain civic groups, will also be utilized in disseminating information about the heart and heart disease.

The campaign will coincide with the initial activity of the Life Insurance Medical Research Fund recently established by 148 life insurance companies in the United States and Canada. This fund will make available over $500,000 yearly for long-term research programs. Grants are being made to medical schools and other research institutions for heart studies.

The booklet, "Your Heart," gives information about the heart and heart disease suitable for an intelligent layman. The statistics in the packet being sent to physicians are presented in the following excerpt from an article entitled "Encouraging Trends in Heart Disease," which appeared in the *Statistical Bulletin* recently published by the Metropolitan Life Insurance Company.

Encouraging Trends in Heart Disease

Measured in terms of sheer numbers of persons affected, heart disease is our most important medical and public health problem. There are today about four million people in the United States who have some form of heart disease, and the number of cases is steadily increasing. Heart disease ranks first in the list of causes of death. It is not surprising, therefore, that there is a widespread impression that the situation with regard to the disease is critical, that the outlook for the patient with heart disease is poor, and that the conditions of modern life are largely to blame. Actually, the situation is much better than appears on the surface, and these current gloomy beliefs about the disease are not warranted by the facts.

It is true that the crude death rate from heart disease has shown a steady increase over the years. The major part of this increase, however, simply reflects the rapidly increasing proportion of older persons in our population. In the past seventeen years, among the millions of persons insured in the Metropolitan's Industrial Department, there has been an almost uninterrupted rise in the crude death rate from the disease, reaching a maximum in 1943, with a total increase of nearly 60 per cent since 1928. As against this large increase, the rate corrected for changes in the age, sex, and color composition of the insured shows a rise of only 12 per cent from 1928 to the maximum in 1943, and the 1945 rate is only 4 per cent above that for the year 1928.

Aside from the aging of the population, there are other factors of importance that have brought about an increase in the *recorded* death rate from heart disease. Unfortunately, it is not possible to "correct" the rate to allow for their effect. Increasingly many deaths, formerly reported as from nephritis or from cerebral hemorrhage, have been more recently ascribed to heart disease because of the changing medical concept regarding the relationship of high blood pressure to these conditions. For, the present concept is that the heart in most such cases is the organ primarily affected by increased blood pressure. Also, as a result of the more accurate determination of the cause of edema (dropsy), a frequent late complication in both heart and kidney disease, many cases with dropsy are now recognized as due to heart failure which formerly would have been ascribed to renal disease.

* * *

Without any allowance for the factors indicated above, there has been a definite reduction in heart disease mortality up to age forty-five. At ages one to twenty-four years, this death rate in recent years among the insured white males has fallen about 60 per cent as compared with 1911-1915. Among young white females the reduction is even larger. At ages twenty-five to forty-four also their death rates have in recent years been lower than at any time since 1911. Among white males twenty-five to forty-four years old, the death rate has been stable for ten years, but the recent level of the rate is well below that for 1911-1915. These declines at ages under forty-five are due chiefly to the decline in the mortality from rheumatic heart disease.

As regards the diseases of the coronary arteries, which account now for a large proportion of deaths ascribed to heart disease, the rapid increase in the mortality from these conditions represents almost entirely the changing diagnostic concepts in heart disease that are reflected in medical terminology. It is noteworthy that, as the mortality from coronary thrombosis and occlusion has gone up, the death rate from myocardial diseases has fallen.

The outlook in various types of heart disease has been shown in recent studies by the Company and by a number of physicians to be much better than has previously been realized. It is found, for example, that a considerable proportion of patients who have suffered an attack of coronary occlusion are still living ten years after the initial attack, and that many of these people are re-

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

DUAL APPROACH SPEEDS PREPAYMENT MEDICAL CARE PROGRAM

A dual approach, the result of months of careful study by a committee appointed two years ago by the House of Delegates, will provide a comprehensive prepayment medical care program for Minnesota within a short time.

This decision was made at a meeting of the House of Delegates of the Minnesota State Medical Association held Sunday, December 22, in Saint Paul. The delegates voted first to authorize the establishment by the Minnesota State Medical Association of a nonprofit corporation, to be known as Minnesota Medical Service; and second, to invite and encourage reliable insurance companies to sell indemnity contracts which offer health, sickness and accident policies that meet definite minimum standards of services and benefits set up by a newly appointed liaison committee of the state association.

It was felt that the undertaking was too large for any one organization to handle if speedy and broad health and sickness protection were to be assured Minnesota citizens, and for that reason the delegates voted to utilize not only the facilities Blue Cross could offer, but also those of established insurance companies whose enthusiastic co-operation is an established fact.

This decision on the part of the delegates might well be spoken of as the "Minnesota Plan" for while it will use different vehicles, there is but a single over-all objective, and that is to offer to the people of Minnesota as quickly as possible a program for budgeted medical care with a broad base and a comprehensive scope, to be sold in packets that will fit the needs of the employe and the employer, and at the same time be acceptable to Minnesota physicians.

Minnesota Medical Service to Begin Shortly

Minnesota Medical Service, a nonprofit corporation created by the medical profession of Minnesota, will come into being shortly when the Articles of Incorporation have been filed with the Secretary of State. The House of Delegates authorized the Council to appoint two physicians from each councilor district, who, in turn, will select three at large, for a total of twenty-one physicians, to serve as incorporators in accordance with the Enabling Act passed two years ago. On this body will fall the responsibility of selecting the first Board of Directors of the new corporation from which its first officers will be chosen. Of primary importance will be the selection, as soon as possible, of an experienced and capable director on whose council the incorporators and later, the Board of Directors, can rely during the corporation's early crucial period.

Subscriptions from Minnesota physicians toward the corporate fund went over the $100,000 mark set by the House of Delegates in May. However, it is not clear that all of the subscriptions which were pledged at the time the Organization Committee was considering recommending an indemnity contract for Minnesota Medical Service, strongly favored by some of the county medical societies, will be honored. For that reason, a recommendation was voted by the House of Delegates to empower the Council to stipulate that the capital fund may be $50,000, or a comparable amount, if that appears expedient, instead of the $100,000 previously specified.

Organizing Committee Presents Final Report

Dr. B. J. Branton, who was chosen as general chairman to head up the work of the Committee on Organization for Minnesota Medical Service, gave a complete report to the House of all the work which his committee had done since its creation. Included in this report were preliminary drafts of the Articles of Incorporation, the proposed agreement with the Minnesota Hospital Service Association which will handle sales promotion, collection of premiums and certain bookkeeping procedures, the two contracts proposed and the schedule of benefits. It was the Committee's recommendation that the final draft of the agreement with Blue Cross as well as the contracts proposed be left until such time as a director had been selected.

The proposed Surgical Contract provides benefits for surgical procedures up to $150 and includes maternity benefits after the contract has been in force nine consecutive months. Service in full to the extent of the benefits under the contract is proposed for the single subscriber whose net income is $1,200 a year or less; and for the subscriber with one or more dependents whose net income is $2,000 a year or less. For subscribers whose income exceeds these amounts, the benefits provided under the contract shall be regarded as partial payments toward the physicians' fees. The monthly charge for a single person has been set at $.85; for a subscriber and one dependent, $1.60; and for a subscriber and two or more dependents, $2.50.

The medical-surgical contract proposed is identical to the surgical contract except that it contains a section providing the following benefits up to a total of $100 a year for the subscriber: $2 per call, beginning with the first call, for medical care in the hospital; $3 per call, beginning with the third call, for medical care in the home; and $2 per call, beginning with the third call, for medical service in the office. Dependents of the subscriber are allowed up to $60 a year at $2 a call, beginning with the third call, for medical care rendered in a hospital. The monthly charge in the case of the medical-surgical contract for the single subscriber has been set at $1.45; for the subscriber and one dependent, $2.60; and for the subscriber and two or more dependents, $4.

To give a supplemental report of the Committee's work, Dr. Branton asked that Dr. A. W. Adson, chairman of a special committee appointed by the Council on December 1, be recognized. He concluded his report by recommending that, in view of the fact that the Committee on Organization had completed its work, it be dissolved. Action was then taken by the House for setting up by the Council of a board of twenty-one incorporators for Minnesota Medical Service.

Two Plans Proposed

Some of the members of the Organizing Committee, as their studies of various voluntary prepayment medical plans in the country have progressed, had come to the conclusion that Minnesota's program would proceed at an accelerated pace if not only the facilities which Blue Cross was willing to offer, but also those of insurance carriers, were utilized.

This was the gist of a report presented to the delegates by Dr. A. W. Adson.

Furthermore, Dr. Adson stated, the Organizing Committee was faced with two divergent viewpoints, both in its own ranks and among the profession at large. Several county medical societies had expressed the opinion in no uncertain terms that an indemnity plan would be more acceptable in their communities as it would relieve the physicians of the responsibility of determining the patient's income level, which is particularly difficult to establish among rural people. Another matter that had to be considered was that no clear-cut legal opinion was forthcoming as to whether Minnesota Medical Service could develop an indemnity program and come under the scope of the Enabling Act.

On the other hand, the committee recognized that within the committee itself, as well as among the profession, were staunch advocates for some type of service plan that would provide complete medical service to the extent of the benefits under the contract to subscribers within a certain income level.

It was to solve the problem of meeting both of these viewpoints among the profession, Dr. Adson said, that the Council at its meeting on December 1 appointed a special committee to explore the possibility of inviting reliable insurance companies to participate in the Minnesota program by writing indemnity contracts which would meet certain minimum standards in services and benefits.

Committee Seeks Insurance Company Proposals

Dr. Adson related what had transpired at the meeting on December 5 when the committee appointed by the Council, all members of the Organizing Committee, had met with insurance company representatives. Several of these companies he stated, are already working with state medical associations. Among those present were representatives from the Employers Mutual of Wausau and the Hardware Mutual of Stevens Point, writing a large number of health contracts in co-operation with the State Medical Society of Wisconsin. Another, the North American of Chicago, has just announced a comprehensive surgical and medical family contract developed in co-operation with the Illinois State Medical Society.

The committee outlined the surgical and medical benefits proposed by Minnesota Medical Service, withholding information about the monthly charges that were contemplated, and asked that each insurance company submit proposals considering these as minimum standards for their contracts. Dr. Adson then presented a chart outlining the proposals which had been submitted following that meeting. Insurance companies not only responded enthusiastically but indicated that they were willing and able to match the benefits proposed and, in many instances, to offer more liberal coverage at lower rates.

On the national scene, he told the delegates, it has become increasingly apparent during the last year or two that large insurance companies have been anxious to co-operate by writing low-cost health, sickness and accident policies, with an over-all coverage which was impossible for medical-profession-sponsored plans to match. It was evident that their motives in evincing this co-operation were not entirely unselfish, Dr. Adson said, but rather it was a concerted attempt on their part to stave off the movement in government circles for compulsory health insurance. Insurance men believe with the doctors that the problem can best be solved by offering such insurance on a completely voluntary basis.

Insurance Men "In Dead Earnest"

That they are in dead earnest has been evidenced, said Dr. Adson, by the many conferences they have had with the Council on Medical Service of the American Medical Association, and also by their co-operative attitude in various state medical association programs.

Just to cite one instance of how successfully the objectives can be attained, Dr. Adson pointed to Wisconsin, which has demonstrated how a physician-sponsored-insurance-carrier program can proceed to spread prepayment medical care to the general public. While some 30,000 contracts have been written under the so-called "Wisconsin Plan" since it got under way in April or May of last year, a great many more than that (probably well over 150,000) have been written as individual contracts under the impetus furnished by the Wisconsin Plan.

After studying all these facts, Dr. Adson said, the committee had come to the unanimous conclusion that it would recommend that two plans be proposed for Minnesota: first, that there be organized immediately a nonprofit Medical Service Corporation, in accordance with the Enabling Act which the medical profession had sponsored; and second, that a broad indemnity insurance program be developed with insurance companies working in close co-operation with a liaison committee of the state association.

Council Takes Action to Spur Program

The committee's recommendations were approved by the delegates and the appointment of the liaison committee was left to the Council. Immediately following adjournment of the House, the Council met in special session and appointed the following committee: Dr. A. W. Adson, Rochester, chairman; Drs. B. J. Branton, Willmar; R. W. Morse, Minneapolis; V. P. Hauser, Saint Paul, and B. J. Gallagher, Waseca.

The Council also asked that each councilor contact and select two physicians from his district, who favor the establishment of the nonprofit corporation, to serve as the incorporators of Minnesota Medical Service. As this article goes to press, these selections are being made, and an important meeting of the incorporators has been scheduled for January 4 in Saint Paul.

DELEGATES HEAR PLEA FOR ESTABLISHMENT OF PRACTICAL NURSE TRAINING SCHOOLS

Following up action taken by the Northern Minnesota and Southern Minnesota Medical Association last fall, Dr. R. F. Hedin, Red Wing, urged the delegates to go on record approving the establishment, as soon as the teaching personnel can be secured and the courses can be set up, of twenty one-year practical nurse training schools to alleviate the critical shortage of nursing personnel in rural areas. The lack of nurses is one of the crucial problems facing the medical profession today, Dr. Hedin said. A report was given on discussions which had taken place by a special committee, composed of representatives from the medical, the hospital, and the nursing professions, which has under consideration the drafting of a bill for the licensure of the practical nurse. It has yet to be determined who shall compose the

Internal Derangement of the Knee

(Continued from Page 44)

that a stiff knee will not result from the operation. Naturally some immediate postoperative stiffening due to pain and lack of use will occur but, barring ankylosis of the knee which results from severe postoperative infection, stiffness of the knee does not occur after operation. It is our duty as physicians to dispel the still prevalent opinion among both laymen and physicians that letting the synovial fluid off the knee will cause stiffness.

Minneapolis Surgical Society

STATED MEETING HELD OCTOBER 3, 1946

The President, Robert F. McGandy, M.D., in the Chair

THE SURGICAL APPROACH TO RENAL AND OTHER RETROPERITONEAL TUMORS

THEODORE H. SWEETSER, M.D.
Minneapolis, Minnesota

Abstract

Three factors are especially important in the surgical approach to any malignant tumor. First it must allow exposure and division of the veins and lymphatics before any tumor cells can be squeezed into them by operative manipulation. Secondly the approach must give the best possible exposure of the tumor and it's surroundings in order to allow better hemostasis and more accurate dissection. Thirdly and less important, overlying tissues and neighboring organs should be damaged as little as possible. Damage to nerve trunks is most serious because of the consequent muscle paralysis. Damage to the neighboring intraperitoneal organs and to the patient's general functions is also serious and may be caused by prolonged exposure and by the manipulation of packs and retractors.

Operation for any mass in the kidney or retroperitoneal tissues should be undertaken with recognition of the possibility of malignancy and with adequate preparation and draping of the field. Malignancy being often in question, exploration is begun through an oblique incision in the flank, and only when malignancy is demonstrated is the incision extended as described.

In cases of malignancy (on the right side, for example) the oblique incision is extended parallel to and between the eleventh and twelfth dorsal nerve trunks across the right rectus muscle about halfway between the navel and the symphysis pubis and extended thence upward close to the median line to the xyphoid. The large triangular flap is lifted laterally and upward over the retracted right rib margin. With sufficiently extensive skin preparation beforehand, the entire incision is made easily while the operator remains in the usual position behind the patient. Using the extraperitoneal layer of fat as a line of cleavage, the peritoneum is pushed aside unopened. The left abdominal wall and abdominal contents enclosed in peritoneum fall away by gravity toward the patient's left, exposing the right renal vessels with very little retraction. We have been astounded at the good exposure and ease of approach to the renal vessels without manipulation of the kidney. We also have been pleased by the prompt, strong healing of the wound.

The incision described above preserves the nerve supply of all the abdominal muscles. The unopened peritoneum helps in control and retraction of the intraperitoneal organs and protects them from infection and damage by evaporation and by trauma of packs and retractors. The lateral posture of the patient and shape of the flap result in better exposure than any other approach because the abdominal contents drop away toward the opposite side with little or no need for retractors, and the area of the renal vascular pedicle comes well up into the wound for accurate and adequate primary treatment.

In cases of papillary carcinoma of the renal pelvis or ureter, one should deal with the lower end of the ureter and ureteral orifice even before dealing with the renal vascular pedicle. That can be done easily with the approach described by extending the midline part of the incision downward to the symphysis as well as upward. That allows one to reach the lower ureter at least as easily as by the midline suprapubic incision of Monsarrat. As suggested by Hugh Cabot in his paper in 1925, there are other conditions in which the advantages of unusually good operative exposure will recommend this approach. I would recommend it particularly for certain cases of tuberculosis and calculous pyonephrosis wherein extensive inflammatory reaction and fibrosis make protection of neighboring organs particularly difficult.

Discussion

Dr. Stanley R. Maxeiner: I talked to Doctor Sweetser about this incision, anticipating its use in a case of hypernephroma. Subsequently I used it with great satisfaction. I could only suggest that the lower end of the incision be curved instead of a sharp angle as the curved flap will undoubtedly heal better than will a sharp-angle flap. Those who observed the use of the incision stated that it was nearer an autopsy exposure than anything they had ever seen. I have subsequently examined the patient and he had primary healing with a completely competent scar.

TRANSTHORACIC GASTRECTOMY

Case Report

STANLEY R. MAXEINER, M.D., F.A.C.S.
Minneapolis, Minnesota

Carcinoma of the cardiac portion of the stomach has until recently been extremely resistant to surgical attack. The abdominal approach has been very difficult and too often productive of poor end results. Only in recent years has it been attacked transthoracically and transdiaphragmatically. This approach has been made

---

Abstract of paper to be published in Journal of Urology.

safer by the use of endotrachial anesthesia which permits compression or expansion of the lung at will. Ohsawa[6], about 1933, performed three transthoracic gastrectomies but none survived. It was not until 1938 that Adams and Phemister[1] reported the first successful transthoracic resection of the distal end of the esophagus and cardiac portion of the stomach with esophagogastrostomy. This patient was reported well without recurrence three years and four months later. Ochsner and DeBakey[5] performed the first similar operation for carcinoma of the stomach.

This operation has now been popularized by Phemister, Garlock, Ochsner and DeBakey, Sweet, Clagett and others. The early mortality was very high but with increasing experience and greater advancements in technique, it has been reduced so that it now compares favorably with similar surgery via the abdominal route.

Bradshaw and O'Neill[2] report a mortality rate of 46.6 per cent in approximately fifty-six patients so treated. Garlock[4] in four years explored twenty-five patients with adenocarcinoma of the pars cardia. Nine were found operable, that is, 36 per cent. There was no mortality in the inoperable group and the nine operable patients received radical surgery with four deaths, that is, 44.4 per cent mortality. Garlock states that from their experience and that of others, a patient with a resectable carcinoma of the pars cardia has a 60 per cent chance of surviving the operation and then an 80 per cent chance of living two years or more. Clagett[3] reports fifty-seven transthoracic operations on the cardia and lower esophagus, of which twenty-four were found to be inoperable and thirty-three underwent resection. There were no deaths among the explored cases; and of the thirty-three who underwent radical resection, five died, a mortality of about 15 per cent. Thus, the mortality of transthoracic gastric operations in his hands does not carry a much greater mortality than carcinomata of the stomach approached via the abdominal route. He states that carcinoma of the cardia occurs in about 10 per cent of all carcinomata of the stomach and that 33 to 60 per cent of carcinomata of the esophagus occur in its lower third.

Because of the fact that carcinoma of the cardia spreads upward toward and into the esophagus and that the reverse is true of carcinoma of the esophagus, both lesions are usually discussed together. There is no block which limits the spread of the disease as occurs at the pylorus. Lesions in this area may require resection of both the stomach and the esophagus, which requirement demands that they be approached transthoracically

The diagnosis of carcinoma is usually made by x-ray examinations. Clinical signs and symptoms may not even suggest the presence of a gastric lesion, but dysphagia suggests a lesion in the esophagus or one in the cardia extending into the esophagus. The gastroscope is probably least valuable in lesions of the cardia, but in the esophagus it may determine the exact area of involvement and, through biopsy, the character of the growth. Lahey has for years advised exploration of gastric lesions of doubtful character. Bradshaw and O'Neill[2] strongly endorse the recommendation of Ochsner and DeBakey that exploration of this obscure area of the stomach is even more imperative. Several writers on this subject recommend preliminary exploration through an abdominal incision but Clagett[3] states that extension of carcinoma of the cardia above the diaphragm can be determined and surgically removed only through a transthoracic incision. On the other hand, the extent of the involvement of the liver and regional glands and the degree of fixation which determine the operability of a carcinoma are just as easily detected through an incision in the diaphragm, with no greater hazard. A preliminary abdominal exploration in the presence of a resectable lesion means two operations or two incisions at one operation and constitutes an unnecessary added load on a patient who is already a substandard risk.

Preliminary preparation of the patient implies a complete evaluation of his examination reports which might contraindicate surgery. Transfusions, high protein diet, vitamins, intravenous fluids, et cetera, should be used to counteract the effect of weight loss, dehydration, debility and anemia. Sulfa drugs and penicillin are favored preoperatively by some. This preparation and careful study demands adequate preoperative hospitalization.

The subject of anesthesia for thoracic surgery will be left for the discussion of our specialist in that field, Dr. Ralph Knight.

The technique of transthoracic resection of the cardia and lower end of the esophagus is not yet standardized, but certain fundamental principles are universal.

After the induction of anesthesia and the introduction of the endotrachial tube the patient is placed on his right side and his position well secured by pillows, sand bags and straps or wide adhesive tape. The left arm should be anchored to a frame at the head of the table. Intravenous needles of competent size should be introduced and the solution kept dripping so that fluid and blood may be given as indicated throughout the entire operation. A catheter with suction is retained in the esophagus to prevent gastric content from entering the pharynx and lungs. The chest area should be prepared widely and draped.

A long incision is made over the ninth rib which is removed subperiosteally from the cartilage anteriorly well back to the spine. The pleura is opened and the ribs widely spread apart and, if necessary, the seventh and eighth ribs may be divided posteriorly to increase the exposure. The lung is permitted to collapse partially and is retracted into the upper chest. The diaphragm may be paralyzed temporarily by injection of the left phrenic nerve as it traverses the lateral wall of the pericardium. Involvement of the esophagus, mediastinal regional glands or pleura can be determined by palpation and vision. The diaphragm is next incised radially in its dome to permit abdominal exploration. Vision of adjacent stomach and peritoneum is now possible and the examining hand may be passed through the rent in the diaphragm and the stomach, liver, regional glands, omentum, et cetera, palpated or visualized. Exploration should determine the operability of the carcinoma and if the lesion is inoperable the diaphragm is sutured and the chest closed. If the lesion is found to be resectable, the rent in the diaphragm is enlarged so as to join the esophageal hiatus. The esophagus is freed and the upper involved area of the stomach and regional glands are liberated. As in any other gastric resection it may be advantageous to include the spleen, omentum and part of the tail of the pancreas in the mass removal. The stomach is clamped below the growth and closed completely. Although the stomach has unusual vascularity, one must be alert not to devascularize it entirely. The right gastroepiploic surely and the right gastric artery if possible should be preserved. The esophagus is divided above the upper limits of the lesion. Light compression about the esophagus above the lesion during liberation of the stomach will prevent expression of gastric content into the pharynx. The cut-off end of the esophagus is now anastomosed with nonabsorbable sutures to the anterior wall of the remaining part of the stomach. Free stomach is brought into the chest to prevent any pull on the line of suture and the diaphragm is closed about the stomach, to which it then is anchored. The tube in the esophagus is now passed into the stomach for the purpose of suction or early feeding. Two rubber tubes are introduced through stab wounds into dependent sites in the pleural cavity. Continual suction for a few days removes pleural fluid and induces expansion of the lung. Bronchoscopic aspiration at the close of the operation may be advisable to remove gastric content from the bronchi.

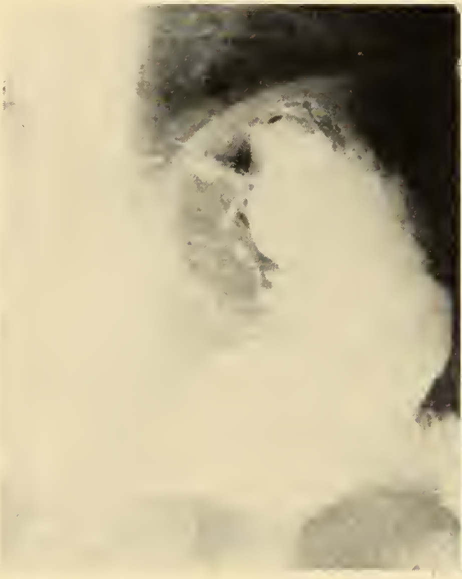

Fig. 1. X-ray shows an extensive carcinoma, causing a large filling defect in the pars cardia of the stomach.

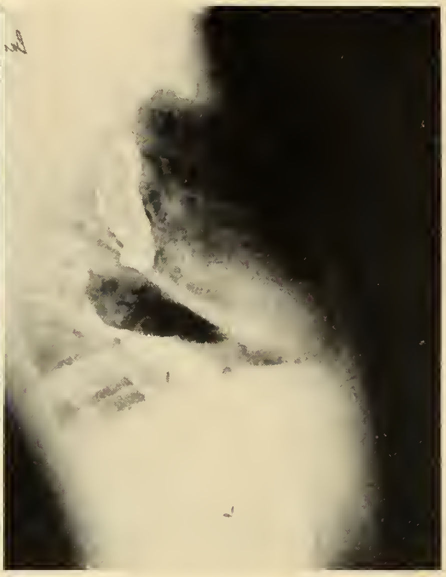

Fig. 2. X-ray shows the slightly dilated esophagus, the anastomosis to the anterior wall of the intrathoracic stomach and the narrowed, tubulated stomach which remains below the diaphragm.

Total gastrectomy, where indicated, has been performed but with almost prohibitive mortality because the first or second loop of jejunum often could not be brought up to the cutoff end of the esophagus without tension and subsequent leak at the line of suture. In such cases Sweet[7] has advised ligation and division of the central vessels of the jejunal loop, with reliance on the marginal vessels for circulation. By this expedient a loop which could be brought through the transverse mesocolon to a point only 1 or 2 centimeters above the diaphragm may now be brought to a level of 3 inches into the chest.

Postoperative care is very important and every effort is exerted to conserve the patient's resources. Administration of oxygen, blood transfusions, parenteral fluids, amino acids and vitamins are even more important now than preoperatively. Suction on the nasal tube and that on the thoracic drains is maintained. In view of the fact that nearly all these operations are done without clamps, there is some soiling; but infection is well borne by the pleural cavity. The liberal use of penicillin has greatly reduced the mortality from infection. Oral fluids and food are given when safety permits.

Report of Case

Mr. A. B., aged sixty, married and a cabinet maker by occupation, was a patient of Dr. Douglas Head and under his observation for several years.

Family and past history is negative except that in January 1946, the patient fell and cracked some ribs.

In March 1946, the patient was examined by Dr. Head at which time he complained of cramps in the legs, numbness in the arms and loss of pep. A vague feeling of distress in the left upper quadrant became worse on lying down. Appetite was good. There was no weight loss nor change in bowel habit. The genitourinary system was normal.

Hemoglobin was 65 per cent. Gastric expression showed no free hydrochloric acid. Total hydrochloric acid was 25. Blood and pus were present.

Roentgenograms of the gastrointestinal tract in May 1946, showed a large mass involving the cardia of stomach producing displacement of the esophagus and a probable very extensive carcinoma of the cardia involving the lesser curvature.

The patient entered Asbury hospital June 4, 1946, where the hemoglobin was found to be 56 per cent; plasma proteins, 5.8 and an electrocardiogram showed left axis deviation. He was placed on a high protein, high caloric diet. Vitamins and blood transfusions were given.

On June 8, 1946, a transthoracic subtotal gastrectomy was performed under endotrachial anesthesia given by Dr. Joseph Baird. The cut-off end of the esophagus was anastomosed with silk to the anterior wall of the stomach and the suction tube passed through into the stomach. Two rubber tubes for suction drained the pleural cavity. The operation time was almost six hours and he was given 2000 cubic centimcters of whole blood during the operation. The blood pressure was 142/75 on entrance to the hospital, 150/80 at the start and 120/60 at the end of the operation. The pulse remained under 90 throughout the whole procedure. Nasal suction was removed in six days and he took food well.

The specimen included 3 inches of esophagus, all of the lesser curvature and most of the rest of the stomach, well distal to the carcinoma, the spleen and a large piece of omentum.

The sloughing and infected neoplasm resulted in increased contamination. The chest suction tubes never drained well and he developed a wound infection and later an empyema. Penicillin and sulfa were given freely throughout most of his convalescence. The chest was repeatedly aspirated and only bloody fluid obtained. On the twenty-fourth day the real abscess cavity was encountered and bloody purulent exudate yielded Gram-positive cocci in clusters and chains. A catheter was introduced through a trochar into the abscess and the cavity irrigated with penicillin. Thereafter recovery was prompt and the patient is well and working every day. He eats well and is gaining weight slowly.

Note.—The patient was shown personally before the Society, together with x-rays before and after his operation and numerous slides photographed from published articles demonstrating different methods of technique.

Discussion

Dr. John R. Paine: One point in the technique which Doctor Maxeiner did not stress and which has been a great help to me is not to transect the esophagus until the two posterior rows of sutures in the anastomosis have been placed. If the esophagus is not transected, it can be pulled upon and released in large measure in tension at the line of anastomosis at the time the anastomosis is being made. It is the policy of all who try to do these operations at the University Hospitals to place two posterior rows of sutures before opening the lumen of the esophagus. The esophagus is then transected in stages as the inner layers of the anterior suture lines are placed. Tension at the line of anastomosis can be relieved by anchoring the posterior wall of the stomach to the parietal pleura of the posterior wall of the chest.

The patient who Doctor Maxeiner mentioned had a carcinoma of the lower middle third of the esophagus. This man died approximately ten days after operation. When he got up out of bed, he collapsed at once. At necropsy, it was found he had a pulmonary embolism. The result of transthoracic resection of the cardia of the stomach and esophagus at the University Hospitals is not as good as any of the series of cases which Doctor Maxeiner mentioned.

As I remember, practically no operations of this type were done at the University Hospitals prior to 1941. Since that time, I cannot give you the cxact figures, but it is my impression that between twenty-five and thirty such operations have been performed. The mortality has been between 20 and 25 per cent. The chief cause of death has been separation of anastomotic suture lines. Empyema has been not an infrequent complication.

Dr. Thomas J. Kinsella: One is somewhat surprised at times at the amount of exposure which can be obtained through a trans-thoracic, trans-diaphragmatic approach to the stomach and esophagus. The stomach may be mobilized almost to the pylorus and brought up into the chest to the apex of the pleura. I now have a patient at St. Mary's Hospital, ten days postoperative, in whom I resected a carcinoma of the mid-esophagus, bringing the stomach into the chest so the anastomosis was made above the arch of the aorta. Because of the position of the tumor only a small amount of the cardia and lesser curvature were sacrificed. The stomach survives such mobilization and elevation better than the jejunum if care is exercised to protect the right gastric and right gastroepiploic vessels which must furnish its sole blood supply. It must also be fixed well up in the chest and to the diaphragm to avoid tension on the anastomosis.

The point which Dr. Paine brought up of using the lower esophagus as a retractor until the first layer of posterior sutures is placed is important. The esophagus is somewhat likc a rubber band and snaps back when released unless fixed in some way. Mattress sutures should be used as simple sutures pull out readily.

All patients subjected to thoracotomy form fluid in the pleural cavity postoperatively. If this fluid is continually removed the pleura will fuse and obliterate the space in a few hours. In all such resections there is some contamination of the pleura and mediastinum for the anastomosis is done by an open method because the blood supply of the esophagus is poor and will not tolerate clamps. Two or three catheters placed in strategic locations will with constant suction keep the fluid out of the chest and permit obliteration of the pleura and walling off of any infection. Both the pleura and mediastinum tolerate contamination well under such conditions.

Postoperatively these patients have some difficulty, dyspnea and so forth, when the stomach becomes distended, but this is a minor matter. Some have temporary difficulty with pylorospasm as the result of vagus section incident to the resection.

This approach has widened our surgical attack on carcinoma of the stomach and opened a new field in treatment of carcinoma of the esophagus in the lower and middle third, esophageal strictures and perforations previously untouched.

Another incision has been used by Sampson and others in the handling of thoraco-abdominal wounds during the recent war. It involves resection of the ninth rib with the patient in the lateral position and extension of the incision forward to the mid-line if necessary. Wide exposure is obtained with better access to the abdominal contents than with resection of the eighth rib.

These procedures are long drawn out affairs but surprisingly well tolerated considering their magnitude. Some patients may be saved in this way who cannot be handled in any other manner. Its wider use is to be encouraged, but abdominal surgeons who plan to employ this approach should give some thought to the physiology of the chest for it differs somewhat from that of the abdomen. Some of the postoperative problems and complications can be avoided by forethought and a little planning.

ANESTHESIA FOR TRANSTHORACIC GASTRECTOMY

RALPH T. KNIGHT, M.D.
Minneapolis, Minnesota

In providing anesthesia for transthoracic gastroectomy, certain requirements must be met. These requirements are quite similar to those for most transthoracic operations, but there are some differences. For most transthoracic operations, especially those involving the lungs, the lung must be collapsed for the convenience of the surgeon for a considerable part of the time. That is not so necessary for the transthoracic approach to the stomach. The lung must be collapsed, but it need be only partially collapsed. It may be packed back out of the way of the surgeon, depending upon how high he needs to work upon the esophagus and that makes little difference in the care rendered the patient by the anesthetist.

The requirements are that the physiology of the patient be kept up, that he have an adequate exchange of gases, presentation of oxygen and removal of carbon dioxide; but there must be quietness of breathing so that the structures may be handled under a minimum of motion. The special requirement in case of work upon the stomach through the thoracic cage is that while, at first thought, relaxation of the abdominal muscle is not of so much importance, in practice, and upon second thought, it becomes of rather major importance. Tension of the abdominal muscles, possibly in the effort of breathing with no aid from the diaphragm, may make a considerable amount of motion and may tend to force abdominal contents up into the thorax to the inconvenience of the surgeon. It, therefore, is even more important in this type of operation on upper abdominal organs through the thorax that the anesthetist carry on respiration for the patient with very little active motion on the patient's part, and that the abdominal muscles be relaxed; in other words, that respiration must be carried on, but general anesthesia must be deep enough so that the abdominal muscles will be relaxed. Especially during the closure of the diaphragm, this relaxation must be provided. It seems in watching the surgeon work that it is just as much of a problem in closing the diaphragm as closing the abdominal wall after an abdominal incision. That involves also the relaxation of the intercostal muscles and quietness of the thoracic wall. While carrying on this controlled respiration, of course, the lung in the open side of the chest is expanded to a certain degree with each artificial inspiration. It does not fully expand even when an amount of pressure with each filling is carried up to 10 to 12 millimeters of mercury. It expands from one-half to two-thirds of its expanded size and may be controlled very easily by a small amount of packing and use of retractors.

There is one difficulty that is sometimes encountered and that is that if there is considerable involvement by inflammation about the esophagus, while this is being freed up, it sometimes happens that the pleura of the opposite side is opened. Both lungs collapse. The patient is then, of course, unable to breath for himself at all and all of his breathing must be accomplished by the anesthetist.

One more difference between operations on the abdominal organs through the thorax and those upon the thoracic organs is that most surgeons like to use a cautery in severing the stomach, either an actual cautery or a diathermy or something of that sort. That cannot be allowed if we are using an inflammable anesthetic because some small leaks from the lungs may be present and if any of this gas should leak out from the lung into the thoracic cavity, it is very apt to catch fire and explode. This problem must be met in one of two ways. Either the surgeon must relinquish his desire to use a cautery and rely on a knife and an antiseptic or an entirely noninflammable anesthetic must be employed.

We like in transthoracic surgery to use cyclopropane. Some anesthetists and surgeons use an ether vapor. The patient's general welfare is not held at quite such a high level if ether is used. Either one is just as explosive. There is no difference. Recently we have been using sodium pentothal, curare, and nitrous oxide, using either a mixture of pentothal and curare in the same syringe which Doctor Baird has developed or using them separately in different syringes. We use nitrous oxide with high enough oxygen so that the welfare of the patient is increased over the usual nitrous oxide anesthesia and still provide enough analgesia so that the amount required of pentothal and curare is definitely reduced. By using this combination we manage to finish a long surgical procedure with an amazingly small amount of sodium pentothal and the patient is ready to wake up at the end.

The anesthetist must be right in on the operation. He must watch the operation as closely as any interested bystander must watch (even if not as carefully as the surgeon), because anesthesia and management of the physiology of the patient must be his concern. His hope is to finish with as light an anesthetic as possible at the end of the operation and allow the patient to wake up quickly so that breathing will be well carried on. The patient's lungs must be filled with helium or nitrogen and adequate oxygen and kept expanded during closure of the chest, except that it must not be fully expanded while the stitches are put into the pleura. As Doctor Maxeiner mentioned, this final lung expansion is very important as one of the means of avoiding atelectasis, which is an especially disagreeable complication following this type of surgery.

Minnesota Academy of Medicine

Meeting of October 9, 1946

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, October 9, 1946. Dinner was served at 7 o'clock and the meeting was called to order at 8:15 by the President, Dr. S. E. Sweitzer.

There were fifty-five members present.

Minutes of the May meeting were read and approved.

The President announced the election of new members at the November meeting.

The scientific program followed.

ECTOPIC KIDNEY WITH HYDRONEPHROSIS

C. D. CREEVY, M.D.

Minneapolis, Minnesota

This report is prompted by the satisfactory result, after fifteen months, of a Y plasty in a young man who had been told by a medical consultant that he had polycystic kidneys and had better sell his farm so that he could lead a less active life. The unusual combination of an ectopic, incompletely rotated kidney with a stricture at the ureteropelvic juncture is also worthy of comment.

Case Report

E. M., a farmer, aged thirty-four, in the period between November 1944 and March 1945 had three attacks of severe pain in the right upper quadrant of the abdomen. Each lasted about two hours until relieved by morphine. He had lost fifteen pounds in weight.

Development and nutrition were excellent. The blood pressure was 140/80. There was an ill-defined, rounded, rather tender mass in the right middle quadrant of the abdomen. Routine studies of the blood and urine gave normal results. The Wassermann was negative, and the urea nitrogen was 19 mgm. per cent.

A plain x-ray of the urinary tract showed the right renal shadow to be somewhat enlarged and low in position. Cystoscopy disclosed a normal lower urinary tract. Clear urine was collected from each kidney. The right renal pelvis was low in position, dilated grade three, and its calices were clubbed and directed medially (Fig. 1). There was a half-inch long constriction of the first portion of the ureter, which had a high origin and followed a course like that seen in horseshoe kidney. The left renal pelvis was normal in size and position, but its calices were directed medially and its ureter, which was intrinsically normal, followed a course similar to that of the right.

It was obvious that there was a noncalculous obstruction at the right ureteropelvic junction, probably due to a congenital stricture. Since the kidneys were so far apart, it seemed likely that the patient had an ectopic, incompletely rotated right, and a normally placed but incompletely rotated left kidney. A plastic operation upon the right ureteropelvic junction was advised.

He returned on June 26, 1945, because of recurrent attacks, the end of the spring planting season, and the advice of his physician.

The right kidney was explored at St. Barnabas Hospital on June 28, 1945, under spinal anesthesia through a low lumbar extraperitoneal approach. There was a low lumbar ectopy with failure of rotation, a sizable anteriorly placed extrarenal hydronephrosis, and a stricture at the ureteropelvic junction which lay upon the anterior aspect of the lower pole of the misshapen kidney.

After a typical Schwyzer-Foley Y plasty and nephrostomy, the kidney was rotated so that the pelvis lay medially, and was sutured in this position. The low origin and shortness of the renal vessels prevented moving the kidney to a higher location. Recovery was retarded by a wound infection, but he was discharged on July 25, in good condition.

He returned on August 9, 1945, because of persistent drainage of pus from the wound. Pale, unhealthy granulations protruded above the surface about the site previously occupied by a penrose drain. These were excised with scissors and moist heat was applied. An excretory urogram showed striking improvement in the hydronephrosis (Fig. 2). Indigo carmine given intravenously did not appear in the wound.

Microscopic examination of the removed tissue showed chronic inflammation; culture yielded aerobacter aerogenes. He was dicharged on August 16 with the wound healing rapidly.

On November 16 the wound was healed, the urine was clear, and he had no complaints. He returned for checkup again on August 29, 1946, without complaints. The urine was microscopically normal, and the urogram showed diminution of the hydronephrosis, return of the calices toward normal, and a funnel-shaped ureteropelvic junction.

Discussion.—The kidneys develop low in the sacral region, in which position the pelves lie anterior to the renal substance. Early in fetal life ascent begins and is accompanied by rotation; both processes end normally with the kidney beneath the diaphragm and the pelvis lying medial to the renal substance. Arrest either of ascent or of rotation, or of both, may occur at any point between the fetal and definitive adult positions. Contact between the two kidneys during ascent results in some form of fusion (horseshoe, L-shaped, sigmoid unilateral fused kidney).

In 37,500 autopsies Bell found ectopic kidneys once in 750 cases. The two sexes were affected about equally; the right side was involved a little more often than the left. Six per cent were bilateral. Crossed ectopy, with or without fusion, is very rare.

The ectopic kidney, despite statements to the contrary, is not *per se* more subject to disease than the normally placed organ, although its vascular supply is often abnormal, a fact which may lead to hydronephrosis from compression of the ureteropelvic junction by anomalous blood vessels. A pelvic kidney may interfere with labor.

According to Bell, hydronephrosis is the commonest renal disorder found at autopsy (3.8 per cent of 32,360 cases excluding those due to stone). Of all the hydronephroses in the series 2.1 per cent were due to noncalculous obstruction at the ureteropelvic juncture; 69 per cent of these resulted from strictures at the uretero-

---

From the Urological Division of the Dept. of Surgery in the Medical School of the University of Minnesota.

pelvic juncture. Other causes of obstruction at this level include accessory blood vessels, distortion of the juncture by sheets of peripelvic fascia, ptosis, inflammatory mucosal polyps, neuromuscular dysfunction, and various combinations of these factors.

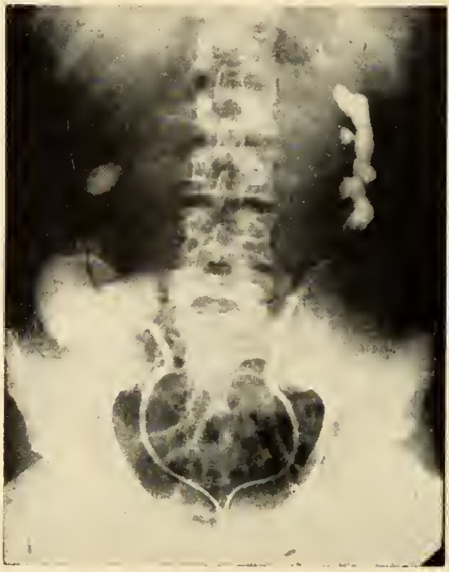

Fig. 1.

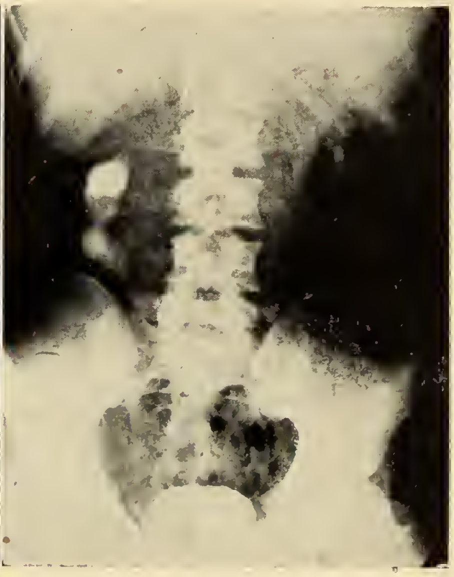

Fig. 2.

Thus we have in the patient under discussion a combination of unusual anomalies: lumbar ectopy, malrotation, and a stricture at the ureteropelvic junction. The striking degree of hydronephrosis with a palpable, tender mass in the right renal area obviated the not uncommon mistake of assuming that a kidney which is normal except for position is causing pain.

Treatment involved two problems: relief of the obstruction and placement of the kidney in as normal a position as the length of its blood vessels would permit. The Schwyzer-Foley Y plasty was chosen because it does not interrupt the continuity of the pelvis and ureter (thus permitting the normal downward progress of peristalsis after operation); because it restores more or less normal relationships between pelves, ureter, and kidney; and because good results have followed its use in a high proportion of my personal series of fifty-eight cases.

Placing the kidney in a normal position is desirable but not essential to a satisfactory result. It is, of course, too soon to classify this patient as permanently cured, but the fact that he has remained free of symptoms for more than a year, coupled with the spontaneous clearing of the postoperative pyuria, and the diminution of the hydronephrosis are all favorable signs. The superiority of preservation of a kidney with almost normal function over nephrectomy in a young man needs no emphasis.

Discussion

Dr. W. F. Braasch, Rochester: Dr. Creevy has reported an interesting type of renal anomaly, namely, an ectopic kidney with malrotation and obstruction at the ureteropelvic juncture. What is of even greater interest is the fact that he succeeded in doing a plastic operation at the ureteropelvic juncture and that a year later he discovered the kidney to have normal function.

It has been my experience that ectopic kidney quite frequently is accompanied by pathologic lesions. In fact, in the majority of cases the urographic evidence may show either malrotation, pyelocaliectasis, pyelonephritis or atrophy. In many cases the renal function is reduced to such an extent that urographic visualization is either absent or very dim and the condition may be easily overlooked in the excretory urogram. When there is obstruction at the ureteropelvic juncture, with intrapelvic retention of urine, the resulting pain may be easily confused with that caused by a diseased appendix. In several cases observed at the clinic the appendix had been previously removed. Dr. Creevy deserves credit because of the excellent results obtained in this case, since the concomitant malrotation, chronic infection and reduction in function often will not permit such excellent results.

I would like to show a series of urograms illustrating the various complications in anomalies of this type, which include the following lesions: pyelectasis, incomplete rotation, bilateral ectopy and stone in ectopic kidney. The kidney may be described as ectopic in case of crossed renal ectopia.

Dr. T. H. Sweetser, Minneapolis: I enjoyed Dr. Creevy's excellent presentation and especially the result of his conservative treatment. I think that is what we should try to accomplish—relief by some conservative measures.

The case I wish to call to your attention was a psychoneurotic patient with pains referred to different systems and treated by various doctors. We were called in consultation at Minneapolis General Hospital in April 1941 because of the presence of pain in the right lower abdomen. Her pain was reproduced at cystoscopy by filling the right renal pelvis for pyelography. Pyelograms showed hydronephrosis of the right ectopic kidney located at the brim of the bony pelvis with short ureter. On exploration, the vessels supplying the kidney came from the iliac artery as well as the aorta. Nephrectomy had to be performed. She is free of pain and of urinary symptoms but has been treated for neurasthenia.

Dr. P. F. Donohue, Saint Paul: Dr. Creevy's presentation of this case was most interesting. Relief of obstruction at the ureteropelvic junction by a type of pyeloureteroplasty which preserved the continuity of the ureter provided an excellent result. Preservation of the continuity of the ureter is certainly desirable but may not always be feasible. In occasional cases, it may be necessary to sever the ureter from the renal pelvis as in the case of obstruction due to stricture when the tissues are extremely thin. It may be required when it is desirable to move the ureteropelvic junction away from the compression effects of renal blood vessels which supply large areas of the kidney and, therefore, must be preserved. Anastomosis of the cut end of the ureter to the pelvis is then performed in a manner to provide a widely opened junction. In a recent case of stricture this method led to a good result and can be recommended in properly selected cases.

REMARKS ON POLIOMYELITIS

MAURICE B. VISSCHER, M.D.
Minneapolis, Minnesota

An epidemic of infantile paralysis is more than a medical emergency in Minnesota. It is a social and political problem as well. There are many reasons for its social implications. The recorded case incidence is more than one per thousand of population and the mortality rate has been 6 per cent of recorded cases. In any case an epidemic of this magnitude of a serious disease would cause great alarm. In the case of infantile paralysis the public reaction has been heightened because of the great publicity which has centered around the disease for a number of years.

A past mayor of Minneapolis hitched his political wagon to the rising star of an Australian physiotherapy nurse who came to the city offering to handle the infantile paralysis problem. It is a misfortune that a few years after she came here the city and state suffered its worst epidemic of all time and a large number of victims have died. Ex-mayor Marvin Kline is now an officeholder in the Sister Elizabeth Kenny Institute.

The present mayor, Hubert H. Humphrey, was unwilling to be stampeded into an unscientific approach to the poliomyelitis problem and recognized that prevention rather than palliative treatment was the ultimate pressing need. He saw that in a disease with a death rate of 6 per cent the first problem was not physiotherapy, great as its value may be at the present time. He therefore established the Minnesota Poliomyelitis Research Commission, with active students of preventive medicine, immunology, pharmacology, neuropathology, physiology, pediatrics and internal medicine undertaking a comprehensive study of the 1946 Minnesota epidemic and of every possible means to prevent its recurrence. This Commission is now hard at work analyzing the 1946 cases and pressing for solutions to the major unsolved problems. The problems of greatest importance seem to me to be: (1) determining the mode of spread of the disease; (2) determining the portal of entry; (3) ascertaining the factors that determine susceptibility; (4) finding useful chemical agents influencing the susceptibility to, and the course of, the disease; (5) elucidating the mechanism of death and finding better methods for its prevention; and (6) improving methods of treatment and rehabilitation. The treatment of the acute phases of poliomyelitis has been very largely neglected by most workers, yet it is of the highest importance, as is evident when one looks at the death rate and when one sees the emotional problems of parents and relatives, and the clinical problems of the patients themselves in an epidemic.

Poliomyelitis is a medical problem of front rank importance only in epidemic situations. Then, however, it is a crucial emergency. The time to work at its solution is not so much during epidemics, although it is essential that many epidemics be studied to learn about the epidemiology, pathogenesis and clinical history of the disease. But the great body of experimental work must be done as a long-time, carefully planned and executed program. This is the objective of the Minnesota Poliomyelitis Research Commission.

Dr. Edwin F. Robb, Minneapolis, then presented his Inaugural Thesis.

ENURESIS

EDWIN F. ROBB, M.D.
Minneapolis, Minnesota

Early medical literature is filled with voluminous reports concerning enuresis, its causes and its cures. Many and varied were the etiological suggestions, the chief of which seem to have been weak kidneys, irritable bladder, too much sleep, not enough sleep, bad behavior, phimosis, and pinworms. The remedies suggested ranged from a wide variety of drugs and elaborate electrical equipment to bribery, ridicule, punishment, and hypnotism.

Most of our advances in pediatric urology have been made during the past twenty years. Helmholz has contributed greatly to our knowledge and conception of infections of the urinary tract. Campbell, White, and many others have been able through the use of improved miniature cystoscopes to add invaluable information concerning pathology of the urinary tract. The roentgenologist, too, has contributed his share with the introduction of excretory or intravenous pyelography and improved roentgenological technique.

With this tremendous increase in information it is only natural that enuresis is viewed in an entirely different light than it was a few years ago. It is no longer considered merely a passing phase of childhood and one that will surely take care of itself as maturation occurs; it is now viewed as a distinct entity, or, at least, as a symptom of an underlying condition that must not be ignored, one that, if allowed to continue, is not only unpleasant, inconvenient, and embarrassing, but may lead to serious psychological, social, and even physical damage to the individual.

That enuresis is not just a disease of childhood is amply proven by Shilonsky et al.,[5] Thorne,[8] and others in reporting on the large amount of enuresis in the recent armed forces. Thorne[8] found that of 1000 consecutive inductees examined 161 had wet the bed until five years of age or over, and that twenty-five or 2.5 per cent of the 1000 men were still enuretics, and unfit for military service. Most of these were in the eighteen- to nineteen-year-old group, but the oldest was thirty-three years of age. Shilonsky,[5] in reporting on 100 cases of enuresis in the Army, found that most of the men had had inadequate care when younger. Most of them had come from rural districts, and had been compelled, as children, to use out-door toilets. Many of them came from large families of limited means, and there was frequently a history of brothers and sisters that also were bed wetters. Furthermore, practically all of them had long since discontinued seeking medical advice because they had received no help. Since adults would naturally be reticent about discussing this situation with their physicians, his conclusion that enuresis is much more common in the adult population than is commonly supposed, seems entirely logical.

The act of urination in an infant is purely a reflex, but in time sufficient maturation occurs for the infant to develop sensations and conditioned reflexes for urinary control. The time that this occurs is influenced by many factors, but in the average child seems to occur at about two and a half years of age for day and three years for complete night control. European observers place these ages at a somewhat lower level. Certainly, if complete control has not occurred by the end of the third year, a diagnosis of enuresis should be made, and a sincere effort be made to correct the situation.

Since it is well agreed that 90 per cent of enuresis may be classified as functional and 10 per cent as due to organic lesions, most of which are of the urinary tract, it is only natural that attention should be directed to the larger group first.

Possibly the first consideration should be an investigation of the child's intelligence. There is much evidence to show that as intelligence goes down, the percentage of enuresis rises. However, there is also ample data to prove that bright and alert children are too frequently afflicted. Despert[3] in a well-controlled study on sixty children in the Payne Whitney Nursery School (all with above-average intelligence) showed an enuretic incidence of 23 per cent. Stockwell and Smith[7] in a study of 100 enuretics with an average age of nine years found 70 per cent to be of average intelligence, with 15 per cent above average and 15 per cent below. Enuresis is usually thought to be more common in the high-strung, nervous type of child, yet Despert[3] found that infants that were alert and reacted most to wet diapers, et cetera, usually had early psychomotor development and early bladder training while those with relatively late psychomotor development had late bladder training. This latter group all ate well, gained well, slept quietly, and were confirmed thumb suckers. It would seem that the lowered intelligence factor has been overemphasized. There is usually little difficulty in housebreaking domestic animals, so with patience and some effort, children of lowered intelligence should be easily taught bladder control.

We have ample proof that an untold number of psychological and psychogenic factors are to be found with a group of enuretics, and that the aid of a psychiatrist is invaluable. Fifty-two per cent of Stockwell and Smith's[7] 100 cases were found to be of a psychogenic nature, and were treated by a psychiatrist. Of these, forty-six were improved or cured. If all the lesser emotional and behavior problems are included in this group, the percentage would undoubtedly be much higher than 52 per cent; yet one wonders if many of the emotional and behavior problems in the mother as well as in the child might not result from the bickering, scolding, and ridicule that so often accompanies enuresis. In studying the histories of several hundred cases of enuresis, one fact stands out more clearly than all others. In fact it seems to be present in some form in all cases. Namely, some mistake or neglect in the original bladder training program of the infant. This may be in the choice of time to initiate the program, the method or consistency of carrying it out, the handling of emotional problems that arise, et cetera. Perhaps in our search for the etiology of enuresis, we have been unable to see the forest for the trees. It seems quite possible or probable that the greatest single contributing cause of enuresis is nothing more that the lack of a definite and intelligent training program for the infant. If true, the fault lies squarely on the doorstep of the pediatrician and the family physician. Rarely does he take the time to outline a good training regime, and emphasize the importance of carrying it out completely and consistently. This is usually left for mothers to learn from various magazines and from relatives and friends. The author readily admits his negligence in this matter, and finds upon discussion of the subject with several other pediatricians that they, too, are equally guilty.

While there are many instances of infants being trained, and with no relapses, in the very early months, it seems reasonable to assume that training should not be attempted until there is sufficient maturation of structures involved to insure a reasonable prospect of success. Statistical data seem to dictate that this time should be not earlier than the eighth month of life nor later than the twelfth month. Best results will be obtained if the training is done by the one person that elicits the most favorable reactions generally in the infant. This is, of course, in most cases the mother. A chair close to the floor where the infant feels secure, in a bright cheerful spot, with a smiling and encouraging mother in attendance is of the utmost importance. Little can be gained if the child is resisting and unhappy. Many methods have been used for training, but the one most likely to succeed is for the mother to put the child on his chair at regular intervals during the day, gradually lengthening the intervals as the child learns control. Accidents are bound to occur, and should be passed over lightly while much praise should accompany successful performance. Diapers should be discarded at this time, and the fact must be recognized that the training of boys requires more patience than does the training of girls. This is due to the fact that boys require two training periods, first in the sitting position and again in the erect position. This may in part account for the supposedly higher incidence of enuresis in boys than in girls.

Night training should not be attempted until daytime control has been attained. When this daytime conditioned reflex is completely established it will tend to carry over into the subconscious mind of the child asleep. Dryness at night can be encouraged by giving milk to the child after his afternoon nap, and by giving a supper relatively low in liquids. If the child is consistently wet at night he should be taken up before the expected time for urinating, but he should be awakened completely, not placed on his chair in a semi-conscious condition. To do this is but to train him to urinate in his sleep. Here again the interval of time should be lengthened as rapidly as possible until it is no longer necessary to awaken him. Our goal, we must remember, is to go through the night without urinating, not merely to have a dry bed.

This may sound elementary to us, but it is of the utmost importance to check every detail with the mother, for this procedure requires a mother or a nurse that is completely convinced of its necessity and one who is patient and willing to follow through with the program. It is sometimes helpful to use an alarm clock to awaken the child at night. The ringing of the clock, or rather the realization by the child that the alarm will awaken him, may speed the development of subconscious inhibitory control. If, however, with intelligent and conscientious effort on the part of the mother or nurse, the physician, and, if need be, the psychiatrist, full continence is not attained by the time a child is four years of age (five years at the latest) one must consider the very likely possibility that an organic lesion is responsible, and enlist the aid of the urologist and roentgenologist.

While it is true that only 5-10 per cent of enuresis is due to organic pathology, it is with this group that we should be most concerned. Even minor organic lesions may eventually lead to serious renal changes and chronic disturbances of micturation in the adult.

Since Campbell's report[2] in 1937 there have been many excellent contributions to this subject by urologists both here and abroad. There is no longer any doubt that a wide variety of organic lesions of the urinary tract are to be found in children, and have, in many cases, proven to be the underlying cause of enuresis. For the most part these lesions are either infections or obstructions or both. In many cases with infections the urine is not only negative microscopically, but will be culture negative as well. Complete and careful urological examination becomes essential as the only means of a definite diagnosis. White[9] emphasizes the importance of looking for minor lesions, especially in the urethra, and feels that failure to find them may account for the majority of so-called failures in treatment. This seems reasonable since we know that psychic influences such as the sound of running water, or the proximity of a toilet has a very much greater effect on the patient with a cystitis or urethritis than on one with a normal urinary tract.

Campbell[2] in 1937 reported a series of 700 children suffering from persistent enuresis. Cystoscopic and urethroscopic examination revealed an amazing amount and degree of pathology. He concluded, "that complete urological examination should be performed if enuresis persists after three to four months of good medical and psychiatric care; that all urological procedure can be carried out in children, and that in many ways they are tolerated better than in the adult." He points out, however, that excretory urographic study should be done first even though in his experience diagnostic help was obtained in only 50 per cent. Spence and Moore[6] in 1939 reported a series of fifty female children from three to fourteen years of age, either with acute pyuria or a history of previous pyuria, 20 per cent of whom were enuretics, 76 per cent showed a chronic urethritis, and in many there was a diminution in the size of the urethra and a loss of its elasticity.

White[10] in 1941 reported a study of 310 cases of enuresis in children at the Princess Elizabeth of York Hospital in London. He emphasized the importance of infection as an etiological factor in enuresis, although only 15 per cent of his cases showed any evidence of infection in the urine. Sixty per cent of his cases were female and 16 per cent definitely followed infectious diseases such as measles, scarlet fever, et cetera. Twenty-seven per cent of the boys in this series showed inflammation and constricture of the external urinary meatus. In girls the external urinary meatus was seldom constricted, but adjacent local inflammation was usually present. Of 220 cases with cystoscopic and posterior urethroscopic examination, 70 per cent showed evidence of inflammation on the front of the trigone and at the internal urinary meatus. Of 150 cases with intravenous urograms, 60 per cent showed variations from the normal in the upper urinary tract, all of which were minor but important as indicating early changes due to inflammatory processes below. White treated this series by dilatation of the urethra, and reported benefit in some degree for 97 per cent. Eighty per cent benefited by one treatment only, 55 per cent ceased to have enuresis for from three months to two years, and 42 per cent continued to have enuresis, but were much improved. Meatotomy was necessary in 70 per cent of the cases in order to pass a sufficiently large sound.

Higgins,[4] too, emphasized the importance of a careful examination of the vulva and urethra in girls, and the external urinary meatus and urethra in boys for signs of inflammation or obstruction, both of which he felt to be a common cause of enuresis.

Brodny and Robins[1] in an excellent article in the *Journal of the A.M.A.* in 1944 recognized the value of early and complete urological study of enuresis. They emphasized the value and advantage of cystography and urethrography over other methods of urological examinations. They believe that it is not only much easier and safer, but in many ways more valuable, since it can be done on younger children and repeated if necessary to watch the progress of a lesion. They also emphasize the necessity of teamwork between the pediatrician or family physician, the psychiatrist, the roentgenologist, and the urologist if the best results are to be obtained in the diagnosis and treatment of enuresis due to organic lesions of the urinary tract.

During the past few years I have sought urological help on a small number of cases of persistent enuresis. They were referred to the late Dr. Ernest Meland, who was very much interested in this subject. Unfortunately there is no record of those patients who failed to show pathology of the urinary tract, but my impression is that the number was small, since most of the group consisted of older children that had resisted all medical and psychiatric treatment.

I should like to present briefly nine cases in which definite disease was found, and to thank Drs. Creevy, Webb, and Smith for making these records available to me. Two of this group of patients have moved from the city, and the end results of the treatment are unknown.

Case 1.—S. S., female, aged twelve, had a history of diurnal frequency and nocturnal enuresis. Cystoscopic examination revealed a granular urethritis, grade 2. Internal sphincter, bladder, and ureteral orifices all appeared normal. Both ureters were catheterized, and specimens collected. Cultures from the kidneys and bladder were negative. Kidneys, ureter and bladder were normal.

Diagnosis: Granular urethritis.

Note: this patient moved out of town in a few weeks, and has not been followed.

Case 2.—C. P., male, aged twelve, had severe eczema as a baby and frequent colds with spasmodic bronchitis. Severe pertussis at seven years, after which he developed severe attacks of asthma and persistent and severe enuresis. Dr. Meland dilated this boy's urethra, and instilled 1 per cent silver nitrate. There was no improvement and two months later he was readmitted for urological study. Cystoscopic examination revealed a normal urethra, but there was hypertrophy of the veru, grade 2, and a marked redundancy of the mucosa at the vesical neck producing an obstruction. Ureteral orifices were normal. The verumontanum was fulgurated down smooth, and the mucosa at the vesical neck was fulgurated by means of strip cautery. A No. 12 catheter was left in the bladder for two days.

Note: For three to four months this patient wet his bed occasionally, but for the past three years he has had no enuresis.

Case 3.—F. B., male, aged ten, had had persistent enuresis since infancy with microscopic hematuria at times. Cystoscopic examination revealed a flap in the urethra attached to the distal portion of the verumontanum, and acting as a valve. K.U.B. and all other findings were normal. The flap was destroyed by fulguration. Diagnosis: Posterior urethral valve.

Note: There was no apparent improvement in the enuresis for one year, at which time it ceased and the patient has had no trouble for two years.

Case 4.—S. H., male, aged seven, had had persistent enuresis since infancy. Cystoscopic examination revealed a normal anterior urethra. In the prostatic urethra there was some lateral lobe intraurethral fullness at the vesical orifice with four slight longitudinal bands radiating from the apex of the verumontanum to the vesical neck producing some constriction at the neck. Around the posterior half of the urethra just below the verumontanum was a shaggy inflammatory collar. The bands in the posterior urethra were fulgurated, strip fulguration was applied to the lateral lobes at the vesical neck, light fulguration of the veru, and the inflammatory collar described was destroyed. Kidney ureter and bladder examinations gave negative findings. A No. 12 catheter was left in for twenty-four hours.

Diagnosis: Posterior urethral valve and hypertrophy of the verumontanum.

Note: This boy was much improved, but was still wetting his bed occasionally when he moved from the city six months later.

Case 5.—L. T., female, aged five, had had enuresis since infancy with diurnal frequency the past two years. Cystoscopy revealed polypoid granulations in the region of the internal sphincter. The bladder was normal. Kidney, ureter, bladder examinations and intravenous urogram showed a normal condition. The urine was microscopically negative, but colon bacilli were found on culture.

Diagnosis: Urethritis and Bacilluria.

Note: This patient has not been seen since hospitalization four years ago. It is therefore assumed that treatment was unsatisfactory. The patient was an only child and the mother was extremely neurotic. She was a greater problem than the child.

Case 6.—M. B., female, aged three, had had enuresis and some diurnal incontinence. There was no history of urinary infection. Cystoscopy was normal except for some inflammatory tags and redundancy of the mucosa in the proximal urethra. A K.U.B. was normal. The urine was normal on culture. The tags and mucosa were fulgurated. This patient was readmitted to the hospital two months later. Dr. Meland's note at this time was as follows: "There was marked improvement for a time, but there has been some recurrence of her symptoms." Cystoscopy again revealed a redundancy of the mucosa with tags in the distal urethra. These tags were fulgurated.

Note: The patient again showed improvement for a time, but now, two years later, has occasional diurnal incontinence and nocturnal incontinence two to three times a week.

Case 7.—K. S., male, aged ten, had had persistent enuresis since infancy. Cystoscopy revealed a hypertrophy of the verumontanum which practically filled the posterior urethra, and there was a moderate redundancy of the vesical neck; otherwise it was normal. K.U.B., et cetera, were negative. The veru was fulgurated, there was a strip cautery of the mucosa at the vesical neck in four quadrants.

Note: The mother states that there was no improvement in this boy's condition for one year. During the next two years there was gradual improvement. For the past two years he has had no trouble.

Case 8.—V. T., female, aged six and one half, had suffered from recurring urinary tract infections and persistent enuresis. The infections responded nicely to chemotherapy, but would recur. K.U.B. was negative, and intravenous pyelogram was normal. Cystoscopic examination was negative except for a urethritis, grade 2. The urethra was dilated to No. 18 French sound and 1 per cent silver nitrate applied to the urethra.

Note: There was no improvement in symptoms, and she has for the past three years been under the care of another physician. The mother reports that there is still no improvement in the enuresis.

Case 9.—S. S., Jr., male, aged nine, had had enuresis and diurnal frequency since infancy. He was the older of two children, and came from a fine, intelligent family. He had become such a behavior problem that he failed constantly in school, had no friends in the neighborhood, and was simply impossible in every way. He had good psychiatric help, and was placed in a new school without benefit. Cystoscopy was negative except for an hypertrophy of the verumontanum that practically filled the posterior urethra and a redundancy of mucosa at the vesical neck. The veru was fulgurated down smooth, and strip cautery carried out in four quadrants in the vesical neck. A No. 12 catheter was left in for twenty-four hours.

Note: This boy showed immediate improvement. He wet his bed occasionally for one month, but has had no enuresis for the past five years. His entire personality has likewise changed. When enuresis ceased, the behavior problem disappeared. His school work has been good, and he can be considered a normal boy in every way.

Comment

Obviously no conclusions can be drawn from such a small series of cases, their chief function being merely to stimulate one's further interest in the subject. It might be noted, however, that there were four girls in this group and five boys. The girls all showed evidence of inflammatory changes in the urethra, and culture of the urine was positive in two of them. Fulguration of granulations and redundant mucous membrane was done in two girls. Results in all four of the girls treated were unsatisfactory. Perhaps better results would be obtained in treating enuresis in girls if we treated them in much the same manner as one would treat a persistent pyuria.

In the boys, urine culture was negative in all. Four showed hypertrophy of the verumontanum, four showed redundancy of the mucous membrane in the posterior urethra, and two showed definite posturethral valves. Fulguration of the obstructive lesions was done in all five with apparent improvement in all. One was completely cured, and three were either much improved or completely cured after periods of from three months to one year. Since all other treatment had failed in these boys for many years, it seems reasonable to assume that removal of the obstructive lesions had a part in their eventual cure.

It has been impossible, in the time allotted me, to go into many phases of the diagnosis and treatment of enuresis. Simple urological procedure such as determination of residual urine, bladder capacity, et cetera, may give invaluable information. Likewise many drugs have therapeutic value. Of these ephedrine and atropine probably take first rank, but even these can be used more intelligently and effectively following a complete urological examination.

Summary

In summarizing we seem justified in the following conclusions:

1. Enuresis is a serious medical problem, and deserves careful study.
2. It is not only a pediatric problem, but may be one for the internist, psychiatrist, roentgenologist and urologist as well.
3. The best cure for enuresis usually lies in its prophylaxis. More attention to bladder-training programs for infants is definitely necessary.
4. Organic lesions of the urinary tract must always be suspected, and urological investigation instituted in those cases refractory to good medical and psychiatric care.

Discussion

Dr. C. D. Creevy, Minneapolis: I believe that all of these patients whom Dr. Robb has discussed were seen by Dr. Meland. I have enjoyed Dr. Robb's paper very much. It seems to me that the pediatrist must cure most of the cases of enuresis because I see very few.

The problem is simpler in the male than in the female. From the urologic point of view one can divide enuresis into two main types: The functional, and the organic. The functional type can be divided into two subgroups: the sound sleepers, and the malingerers or psychiatric problems.

Most of those whom I see appear to be sound sleepers. The children have trouble only at night. The urine is normal and the urological investigation shows nothing abnormal. One can relieve most of these patients with the Cunningham clamp or the Foley artificial sphincter. If the child and parents are co-operative, the device needs to be used only for a comparatively short time after which a habit seems to be established, and the difficulty straightens around.

The malingerers are those patients who can be recognized readily by an interview. Characteristically, the child or the mother, or both, are resistant to and rather resentful of, all suggestions and betray this fact by their attitude. These people, of course, belong in the hands of the psychiatrist.

Patients in the organic group are troubled day and night. Dr. Robb has covered this group pretty thoroughly. It includes patients with lesion of the nervous system, such as spina bifida, spina bifida occulta, and various other congenital disorders; those with local irritative lesions in the urethra; and an occasional patient with an ectopic ureteral orifice. This last group consists entirely of girls.

One serious problem from the point of view of the urologist is the difficulty of examining the prostatic urethra satisfactorily in an infant or young boy. The cystoscopes are so small that the objective of the telescope, and the light, necessarily come too close to the mucous membrane of the prostatic urethra, which then tends to shut off the light by the objective so that vision is relatively poor.

Dr. W. F. Braasch, Rochester: I appreciate the opportunity of hearing, not alone the thorough review of the subject of enuresis by Dr. Robb, but also the excellent discussion by Dr. Creevy. I can add very little to Dr. Creevy's remarks. I might say, however, that the urologist has for a long time recognized the existence of etiologic factors of enuresis such as Dr. Robb has cited, but apparently the pediatrician has not. In fact, Dr. Robb is the only pediatrician to my knowledge who recognizes the frequent existence of urologic lesions to account for enuresis and who has written a paper describing them. I trust that he will read this paper before pediatric societies so that his colleagues may be influenced to look for the lesions in the urinary tract which he has described.

Although many cases of enuresis undoubtedly are of a functional nature, the possibility of an organic lesion must be considered, particularly if the symptoms persist beyond the age of puberty. There is one lesion which I would like to mention particularly, namely, dysfunction of the muscles at the neck of the bladder. This lesion is characterized by relaxation of the muscles in this area extending into the adjacent urethra, and it usually can be recognized on cystoscopic examination. Another lesion which always should be excluded is a pin-point meatus at the external urethra. It is not an infrequent cause of enuresis.

The treatment of functional enuresis mentioned by Dr. Creevy is an excellent one, namely, the penile clamp. This has been applied in several cases to my knowledge, with excellent results.

Dr. T. H. Sweetser, Minneapolis: I was glad that Dr. Robb mentioned the training of the parents. In the cases I have seen, the training of the parents and improvement of the environment at home have been important aids in the care of the patients. Hospitalization as a means of changing environment has sometimes helped. Dr. Creevy and Dr. Robb have covered the subject well, but there is just one point I want to emphasize.

Dr. Robb mentioned the importance of urinary infection. After removing any obstructions, local treatment of the posterior urethra and chemical treatment of the infection will clear up the difficulty. But many urinary infections are treated only until symptoms are relieved and urine has become clear; the trouble then recurs with the first intercurrent infection or lowering of the patient's resistance. The infection should be treated until the urine is sterile by culture to give the best chance of permanent cure.

Dr. Alexander Stewart, Saint Paul: I think a good deal as Dr. Robb does about the importance of the functional side. I had a boy in the office this afternoon who has just recovered from polio; while he was in bed for three weeks with polio he never wet the bed, but as soon as he was released from quarantine he started again having enuresis the same as before his illness.

I wish to congratulate Dr. Robb on his fine thesis and I believe that from now on I will refer more of my patients who do not respond to general and psychiatric treatment to the urologist for investigation.

Dr. Robb, closing: I wish to thank my discussants for their generous words. Undoubtedly, most cases of enuresis are functional in origin, but I wish to emphasize again the importance of searching for organic causes. We have, I think, been very negligent in our institution of bladder-training programs. Obviously, we do not want to create a behavior problem as well, but it is amazing how easily many children are trained when this program is started when the infant is only ten or twelve months of age.

The meeting adjourned.

A. E. Cardle, M.D., *Secretary*

Because of peculiarities in its pathology and epidemiology, tuberculosis, especially the pulmonary form, has attained world-wide prevalence. The mode of transmission is simple, and while there are great variations in susceptibility, no class or subdivision of mankind is immune. These peculiarities make it reasonably certain that no nation could eradicate the disease and by artificial barriers prevent its introduction from without. Even if such procedures were theoretically possible, the limitations which they would place upon travel and commerce would make them impracticable.—James A. Doull, M.D., NTA Transactions, 1946.

WOMAN'S AUXILIARY

Blue Earth County

The Blue Earth County Medical Auxiliary entertained the Redwood-Brown and Nicollet-LeSueur auxiliaries on December 7.

After a joint dinner with their husbands at the Saulpaugh Hotel, the fifty wives were guests at the home of Mrs. Roger Hassett.

Mrs. Roger Engel spoke on Germany, and Mrs. Walter Kaufman reported on the State Board Meeting held in Saint Paul, December 6. Mrs. Kaufman was appointed chairman of the Blue Earth County Cancer Society.

Business meetings of the three county organizations were held after the program. Mrs. George Penn presided in the absence of Mrs. Troost, the president.

Hennepin County

The Hennepin County Medical Auxiliary held its annual Christmas party in the Medical Arts Lounge, December 6.

Mrs. Jessie D. Hamer, Phoenix, Arizona, president of the Women's Auxiliary to the American Medical Association, and Mrs. Melvin S. Henderson, Rochester, Minnesota, state president, were guests of honor.

Reading of the play, "The First Christmas Tree," was given by Mrs. Leonard Arling, followed by a program of Christmas music.

Mrs. Elmer O. Dahl and Mrs. Arthur A. Wohlrabe were tea chairmen for the day.

Olmsted-Houston-Fillmore-Dodge Counties

The Olmsted-Houston-Fillmore-Dodge County Auxiliary again sponsored the Christmas Seal essay contest in the Junior and Senior High School in Rochester, awarding a $5.00 prize for the best original essay in each age group. The Auxiliary also aided in the sale of Christmas seals by staffing booths in the downtown hotels.

Mrs. B. M. Black is directing the collection of medical and surgical instruments and medical supplies to be sent overseas to the needy.

Dr. A. W. Adson addressed the auxiliary on the "Minnesota Plan for Pre-payment Medicine," at the fall meeting. A tea and social hour followed.

Wright County

The Wright County Medical Auxiliary held its fall meeting October 14 at the home of Mrs. W. P. Anderson, Buffalo.

Bandages were made for the Cancer Society, and the auxiliary subscribed to *The Bulletin.*

A turkey dinner was served to the members and their husbands by Mrs. John J. Catlin of Buffalo.

The health of all peoples is fundamental to the attainment of peace and security and is dependent upon the fullest co-operation of individuals and states.—Constitution of the World Health Organization, U.N.

AMERICAN ACADEMY OF ARTS AND SCIENCES OFFERS FRANCIS AMORY PRIZE

In compliance with the terms of a gift under the will of the late Francis Amory of Beverly, Massachusetts, the American Academy of Arts and Sciences offers a substantial prize for outstanding work addressed to the alleviation or cure of diseases affecting human reproductive organs. The gift provides a fund, the income of which may be awarded at seven-year intervals "as a prize and gold medal, or other token of honor or merit," to any individual or individuals for work of "extraordinary or exceptional merit" in this field. In case there has appeared work of a quality to warrant it, the next award will be made in 1947. Awards will be made for what in the judgment of the Committee on the Amory Fund appears to be the most outstanding contribution or contributions in the field as outlined and as based on published work and recognized accomplishment for the current seven-year period.

No formal applications and no essays or treatises from individuals are solicited, but suggestions will be welcome from any appropriate source that will be of aid to the Committee in making a wise selection.

Recommendations may be addressed to Secretary, Amory Fund Committee, American Academy of Arts and Sciences, 28 Newbury Street, Boston, Massachusetts.

NATIONAL CONFERENCE ON MEDICAL SERVICE

The twentieth annual meeting of the National Conference on Medical Service will be held at the Palmer House, Chicago, on February 9. Registration will commence at 9 a.m., and the program will include discussions in the fields of national affairs, economics and medical education. All physicians are invited to attend; there is no registration fee. Dr. Cleon A. Nafe, Indianapolis, is president of the Conference and Creighton Barker, New Haven, is secretary.

CHICAGO MEDICAL SOCIETY

The third annual clinical conference of the Chicago Medical Society will be held at the Palmer House, Chicago, March 4-7, 1947. The previous two conferences have warranted the continuance of the meeting, the program of which is selected particularly for the general practitioner. Scientific exhibits from Chicago and adjoining medical centers and commercial exhibits will be included in the program. All physicians are invited to attend. Further information may be obtained from the Society Office, 30 No. Michigan Avenue, Chicago 2, Illinois.

PHILADELPHIA SEMINAR IN RADIOLOGY

The second annual Philadelphia postgraduate seminar in radiology will be held March 30 to April 4, 1947. The course is sponsored by the American College of Radiology and the Philadelphia Roentgen Ray Society.

Registrants will be limited to one hundred, and preference will be given to members of the American College of Radiology who served in World War II. The tuition fee will be $50.00.

Interested radiologists should contact the office of the American College of Radiology, 20 No. Wacker Drive, Chicago 6, Illinois.

MINNESOTA MEDICAL SERVICE

At a meeting held in Saint Paul on January 4, 1947, the articles of incorporation for a non-profit organization to be known as Minnesota Medical Service, Inc. were signed by twenty-one incorporators, and a board of eleven directors was elected.

Dr. Olaf I. Sohlberg, Saint Paul, was named president of the board; Dr. R. R. Cranmer, Minneapolis, vice president; Dr. C. A. McKinley, Minneapolis, secretary; Dr. W. A. Coventry, Duluth, treasurer. Other board members are: Dr. E. C. Bayley, Lake City; Philip G. E. Hoeper, Mankato; Dr. J. F. Norman, Crookston; Dr. E. M. Hammes, Saint Paul; Dr. E. J. Simons, Swanville; Dr. L. L. Sogge, Windom, and Dr. W. W. Yeager, Marshall.

ANNUAL COUNTY OFFICERS MEETING

Officers of all component medical societies of the Minnesota State Medical Association are reminded to keep open Saturday, March 1, 1947, which is the date selected by the Council for the Annual County Officers Meeting. County officers will convene this year at Hotel Lowry,

(Continued on Page 100)

Glenwood Hills Hospitals

New and modern hospitals beautifully located amid the rolling hills of Golden Valley

For the Treatment
of NON-SURGICAL
and NON-INFECTIOUS
DISEASES

Only ten minutes from the Minneapolis loop, the hospitals have all the advantages of a rural setting. The spacious and convenient arrangement of physical plants makes the proper classification of patients possible. The latest in specialized and scientific treatment is emphasized at each of seven separate stations. Every facility for comfort and care is assured the patient. Available to all reputable members of the medical profession.

Operated in connection with HOMEWOOD HOSPITAL

School of Psychiatric Nursing

A course in nursing offers training in a highly paid profession.

Students work with skilled professional men and women.

It's the best preparation for marriage.

It's a profession not affected by depressions.

A one year course in our school of psychiatric nursing is available to eligible applicants. All phases of the subject are skillfully presented by a capable and experienced faculty.

Classroom and laboratory studies are combined with an interesting program of actual work on the wards.

Here's an opportunity to obtain a useful higher education—and at the same time prepare for a highly paid interesting and respected career. Tuition free. Class pin, a diploma and cape are awarded on completion of the course.

Classes begin in January, June and September.
June class now being organized.

Write for particulars. Director, School of Nursing

Glenwood Hills Hospitals, 3501 Golden Valley Road, Route Seven, Minneapolis, Minnesota

Season of Storm

CAUGHT in the storm center of the menopause—bewildered by vasomotor disturbances, mental depression, pain and tension—many patients may be restored to comparative tranquillity by well timed estrogenic therapy.

When you base your treatment on an estrogenic product of unquestioned purity and potency, you can feel certain you have given your patient the best assistance possible through medication.

Physicians using Solution of Estrogenic Substances, Dorsey, may rest upon that certainty...for this product is manufactured under rigidly regulated conditions . . . to meet the highest standards of the industry.

A reliable product . . . judiciously administered . . . receding menstrual "storm" symptoms.

SOLUTION OF Estrogenic Substances DORSEY

ANNUAL COUNTY OFFICERS MEETING

(*Continued from Page 98*)

Saint Paul. The program begins at 2 p.m. and will end with a banquet at which an outstanding speaker will be selected to address the delegates.

MINNESOTA PATHOLOGICAL SOCIETY

The regular meeting of the Minnesota Pathological Society of the University of Minnesota Medical School, was held on Tuesday evening, December 17, in the Medical Science Amphitheater. The speaker was Dr. Edith L. Potter, of the University of Chicago. Dr. Potter's subject was "The Pathologist's Contribution to the Clinical Diagnosis of Disorders of the Newborn."

GOODHUE COUNTY SOCIETY

Dr. Grant F. Hartnagel was elected president of the Goodhue County Medical Society at the annual meeting held at the St. James Hotel on December 6. Other officers are Dr. Martin G. Flom, vice president; Dr. James F. Brusegard, secretary-treasurer; Dr. Raymond F. Hedlin, delegate to the State Medical Association, and Dr. McGuigan, alternate delegate.

Dr. Woodward L. Colby, of Saint Paul, discussed a pediatric survey which will be conducted by pediatricians of the state.

INTERURBAN ACADEMY OF MEDICINE

The annual election of officers of the Interurban Academy of Medicine was held at the Hotel Spalding in Duluth on November 20. The new president is Dr. Philip F. Eckman, Duluth, who succeeds Dr. H. A. Sincock, of Superior. Dr. Conrad Giesen, of Superior, was elected vice president, and Dr. Henry E. Bakkila, of Duluth, was made secretary-treasurer, replacing Dr. Herbert P. Christianson, of Superior. Dr. Richard Bardon, of Duluth, was elected to the board of censors for a three-year term.

Speakers at the meeting were Dr. Giesen and Dr. Frank J. Hirschboeck of Duluth.

RAMSEY COUNTY SOCIETY

The Ramsey County Medical Society at its meeting in Saint Paul named Dr. Clayton K. Williams, Saint Paul, as president-elect to take office in 1948. The president for the ensuing year is Dr. John M. Culligan. Other officers who assumed their duties on January 1 are Dr. Lyman R. Critchfield, vice president, and Dr. Laurence D. Hilger, secretary-treasurer.

A feature of the meeting was a symposium of the recent polio epidemic. Discussion leaders included Dr. Robert B. J. Schoch, Saint Paul city health physician, Dr. Wallace Cole, Dr. P. K. Artz and Dr. Frank Hedenstrom. About 149 members of the society attended.

REDWOOD-RENVILLE COUNTY SOCIETY

Dr. Ralph E. Erickson, of Hector, was elected president of the Redwood-Renville County Medical Society

(*Continued on Page 102*)

The newly diagnosed diabetic and Globin Insulin

WHEN DIETARY MEASURES ALONE cannot control a recently established case of diabetes and insulin must be resorted to, *one daily injection* of intermediate-acting 'Wellcome' Globin Insulin with Zinc will often prove both adequate and beneficial. This simplified regimen can be initiated in the following manner:

ESTIMATING THE DOSAGE: The simplest method is to start with 15 units of Globin Insulin and increase the dosage every few days, as required. A closer estimation is obtained by quantitative sugar determination of a 24-hour urine specimen. For the initial dosage, ⅔ of a unit of Globin Insulin is given for every gram of sugar spilled in 24 hours.

Both diet and dosage must subsequently be adjusted to meet the needs of each individual patient.

ADJUSTING THE DIET: In general it has been found that a good carbohydrate distribution for the patient on Globin Insulin consists of 1/5 of the total carbohydrate at breakfast, 2/5 at the noon meal, and 2/5 at the evening meal. Any tendency toward midafternoon hypoglycemia may usually be offset by giving 10 to 20 grams of carbohydrate between 3 and 4 p.m.

This starting diet may subsequently be adjusted as required to suit the needs of the patient. Final adjustment of carbohydrate distribution may be based on fractional urinalyses.

ADJUSTING TO 24-HOUR CONTROL: Simultaneously adjust the Globin Insulin dosage to provide 24-hour control as evidenced by a fasting blood sugar level of less than 150 mgm., or sugar-free urine in the fasting sample.

'Wellcome' Globin Insulin with Zinc is a clear solution, comparable to regular insulin in its freedom from allergenic properties. Available in 40 and 80 units per cc., vials of 10 cc. Accepted by the Council on Pharmacy and Chemistry, American Medical Association. Developed in The Wellcome Research Laboratories, Tuckahoe, New York. U.S. Patent No. 2,161,198. LITERATURE ON REQUEST.

REDWOOD-RENVILLE SOCIETY

(Continued from Page 100)

at the annual business meeting held in the community hall at Morgan. Dr. Ralph E. Billings, of Franklin, was elected secretary.

Following the dinner and meeting, the twenty-two members who attended were entertained at a social gathering at the home of Dr. and Mrs. William E. Johnson in Morgan.

ST. LOUIS COUNTY SOCIETY

Results of the annual election of officers of the St. Louis County Medical Society, which was conducted by mail balloting were announced at the annual banquet held at the Northland Country Club at Duluth on December 12. The president-elect is Dr. Peter S. Rudi, of Duluth. Dr. Elizabeth C. Bagley, Duluth, was reelected secretary-treasurer, and Dr. Reginald A. Salter, Virginia, vice president. Dr. Daniel W. Wheeler, Duluth, is the 1947 president, succeeding Dr. Paul G. Boman, Duluth.

Dr. Gerhard von Glahn, professor of political science and economics at the Duluth State Teachers College, spoke on "The European Scene Today."

WASHINGTON COUNTY SOCIETY

At the annual meeting of the Washington County Medical Society, the following officers were elected for 1947: President—Francis M. McCarten; first vice president—Russell E. Carlson; second vice president—Emmett R. Samson; secretary-treasurer—E. Sydney Boleyn; delegate—E. Sydney Boleyn; alternate delegate—Wade R. Humphrey; censor for 1947, 1948, 1949—R. J. Josewski, all of Stillwater.

Heart Disease

(Continued from Page 73)

stored to full or partial working capacity. Similarly, studies of children attacked by rheumatic fever show that more than 90 per cent of those who escape serious heart damage lived ten years or longer, and even among those with heart damage a great majority are living ten years after onset. Those without serious heart involvement can usually lead normal lives, with little restricton. This applies also, in considerable measure, to those with damaged hearts, although they must avoid certain types of occupations.

Altogether, then, there is little cause for alarm over the situation in heart disease today. The great bulk of the deaths from this cause occur in older people. It is necessary, of course, to see that elderly heart disease patients are properly cared for. Relatively few of them, however, require or can afford expensive hospital or institutional care. Many cardiacs in the older age groups can live happy useful lives in their own households. Their social, economic, and cultural problems are often more important than their medical problems. The special types of facilities required to cater to these people are in many instances a responsibility of the community.

to combat

depression associated with

persistent pain...

Many patients suffering from persistent pain are subject to attacks of depression characterized by deep apathy and emotional exhaustion. Thus, pre-existing neurotic tendencies may be exaggerated and the pain threshold progressively lowered.

By restoring morale and optimism, Benzedrine Sulfate will often effectively combat the depression which may complicate the management of painful conditions. Needless to say, Benzedrine Sulfate is not indicated in the casual case of low spirits, as distinguished from true mental depression.

Of General Interest

Dr. Henry P. Linner, Minneapolis, has been elected surgeon for the Hamilton Fish Camp No. 7, U. S. Spanish War Veterans.

* * *

The regular quarterly chest clinic conducted by the Rochester Department of Health, was held at the city hall on December 3. Dr. Carl Pfeutze, superintendent of the Mineral Springs Sanatorium, was in charge.

* * *

Dr. Alfred W. Adson, Rochester, was guest speaker at the meeting of the Four County Medical Auxiliary held in Mayo Foundation House on November 29. Dr. Adson discussed prepayment medical care.

* * *

Dr. Clyde E. Wilson has closed his hospital at Blue Earth after more than thirty years of operation. The termination of his hospital activities will not affect his private practice, which will be continued.

* * *

Dr. Ernest F. Cowern, village doctor at North Saint Paul for the past forty-three years, was guest of honor at a dinner sponsored by fellow lodge members on December 13.

* * *

Dr. Orville J. Swenson, of Waseca, recently underwent surgery at Rochester for the correction of two slipped discs in the upper part of his spine. Dr. Swenson expects to be out of practice for about two months.

* * *

Dr. William H. Hengstler, specialist in nervous and mental diseases, discussed the "Emotional Effects of Children's Experiences" at the December meeting of Section 1 of the Child Psychology Study Circle of Saint Paul.

* * *

Dr. M. M. D. Williams, of the Mayo Clinic, has returned from Chicago, where he assisted with the examinations for the American Board of Radiology. Dr. Williams also attended the meeting of the Radiological Society of North America.

* * *

Organization of a Minnesota Chapter of the American College of Physicians and Surgeons has been completed. Dr. Fred Benn, of Minneapolis, was elected president and Dr. Albert E. Ritt, of Saint Paul, secretary-treasurer.

* * *

A tuberculin test was conducted recently by Dr. Kathleen Jordan, of the Minnesota Public Health Association, at the public schools at Willmar. About 660 pupils in the first, sixth, ninth and twelfth grades were tested.

* * *

Dr. Louis R. Buie, of the Mayo Clinic, has been in Chicago for the meetings of the Judicial Council, the Committee on the Revision of the Constitution and By-laws, and the House of Delegates of the American Medical Association.

* * *

Dr. Harry B. Zimmerman, Saint Paul, was re-elected recorder of the Western Surgical Association at the annual meeting held in Memphis, Tennessee, during the first week of December. Dr. Frank C. Mann, of Rochester, was elected first vice president.

* * *

Under the will of the late Dr. Julius A. Hielscher, Mankato, two hospitals are included as beneficiaries. One-half of Dr. Hielscher's estate, which is in excess of $60,000, goes to St. Joseph's Hospital and one-fourth to Immanuel Hospital, both in Mankato.

* * *

Announcement has been made of the appointment of Dr. Charles W. Mayo, of Rochester, as chairman of a nineteen-member advisory committee on medical care for veterans by the Veterans Administration in Washington, D. C.

* * *

While Dr. H. Cope has been interning at Bethesda Hospital in Saint Paul, Mrs. Cope, who is a pianist, has been completing her musical studies at the McPhail School of Music in Minneapolis. On November 14, Mrs. Cope played her graduation recital.

* * *

Dr. Andrew Gullixson, who has been in medical practice in Albert Lea for the past forty years, is assembling a history of the early doctors of Freeborn County which will be included in the History of Medicine in Minnesota.

* * *

Correction—Due to a printer's error, the amount of the Van Meter Prize Award for 1947 was incorrectly listed in the announcement which appeared in the November number of Minnesota Medicine. The amount of the Award is $300.00.

* * *

While on a brief visit at the Mayo Clinic, Dr. V. G. Vaishampayn, chief medical officer of the N. W. Wadia Charitable Hospital at Shaolpaur, Bombay Presidency, India, completed the arrangements for some of the fifty-four doctors whom the India government is sending to America on fellowships to study at the Clinic.

* * *

Dr. John Collin Hays, formerly of Saint Paul, who is a ward officer at Mason General Hospital, Brentwood, New York, has been promoted to the rank of captain. Dr. Hays took his B.A., M.B., and M.D. degrees at the University of Minnesota and served both his internship and residency at the Minneapolis General Hospital.

Prevent INFECTION *with* MERCUROCHROME

(H. W. & D. brand of merbromin, dibromoxymercurifluorescein-sodium)

Extensive use of the Surgical Solution of Mercurochrome has demonstrated its value in preoperative skin disinfection. Among the many advantages of this solution are:

Solvents which permit the antiseptic to reach bacteria protected by fatty secretions or epithelial debris.

Clear definition of treated areas. Rapid drying.

Ease and economy of preparing stock solutions.

Solutions keep indefinitely.

The Surgical Solution may be prepared in the hospital or purchased ready to use.

Mercurochrome is also supplied in Aqueous Solution, Powder and Tablets.

The Hennepin County Medical Society was addressed by Dr. Nils Westermark, x-ray chief at the University of Stockholm, at their meeting on December 9 in the Medical Arts Building.

Dr. Westermark, who discussed bronchial cancer, is visiting American medical schools and has lectured at the University of Minnesota, the Mayo Clinic in Rochester and at the meeting of the Radiological Society held in Chicago recently.

* * *

Educational talks on cancer will be given by Duluth members of the St. Louis County Medical Society on request at various clubs and fraternal meetings throughout the city. The Duluth Chapter, Minnesota Cancer Society, is sponsoring these talks. Among the doctors already having given their services for this purpose are Dr. Charles Bagley, Dr. Duncan V. Luth, Dr. Karl Johnson, Dr. Clarence H. Christensen, Dr. John D. Barker and Dr. Henry G. Geronimus.

* * *

Support of legislation giving counties or groups of counties the authority to establish local health departments, which is to be presented at this session of the legislature, is urged by Dr. Donald A. Dukelow, head of the health and medical care division, Minneapolis Council of Social Agencies, and vice president of the Minnesota committee on local services.

According to Dr. Dukelow, a survey made in 1942 revealed that only 34 per cent of Minnesota's population was served by local full-time health officers.

* * *

Drs. John J. Bittner and George Crane Christian, cancer research specialists at the University of Minnesota, and Dr. Robert A. Huseby, fellow of the International Cancer Research Foundation, at the University, attended the conference on Nutrition in Relation to Cancer which was held in New York City on December 6 and 7.

The conference was sponsored jointly by the New York Academy of Sciences and the Panel on Nutrition, Committee of Growth, National Research Council.

* * *

Specially prepared films are being produced by the McGraw-Hill Book Company for supplementing the use of a *Textbook of Healthful Living,* by Dr. Harold S. Diehl, dean of medical sciences at the University of Minnesota Medical School. The 16 mm. sound-motion pictures, illustrating such subjects as Body Care and Grooming, Personal Health, Sex Education, Mental Hygiene, et cetera, present this information in an entirely factual manner, and the innovation is said to be of value in explaining the more difficult text matter.

(Continued from Page 112)

Dr. Manfred W. Comfort, of the Mayo Clinic, presented a paper on "Gastric Acidity Before and After Development of Gastric Carcinoma" at the recent conference on gastric cancer held at the Billings Hospital, Chicago University. The paper was co-authored by Drs. Mavis P. Kelsey and Joseph Berkson, both of the Clinic.

The conference was attended by about 125 physicians, research workers and representatives of cancer research foundations. Among them were Drs. Berkson, Frank C. Mann, George M. Higgins, John R. McDonald, Harold L. Mason and Hugh R. Butt, all of Rochester.

* * *

The first dinner meeting of the general medical faculty of the University of Minnesota since the end of the war was held in Coffman Memorial Union on Monday evening, December 9.

Major school developments during the past year were outlined by Dr. Harold S. Diehl, dean of medical sciences, who also announced future plans.

A report of the status of fund drives for the proposed Mayo Memorial Building to be constructed on the university campus was made by Dr. Donald Cowling of Saint Paul, who is chairman of the Memorial Committee.

* * *

At the annual meeting of the American Public Health Association in Cleveland in November, five members of the staff of the University of Minnesota Medical School were elected to office in the organization. Dr. Harold S. Diehl, dean of medical sciences, Dr. Gaylord Anderson, head of the School of Public Health, and Dr. Albert J. Chesley, clinical professor emeritus of public health and secretary of the Minnesota State Board of Health, were elected to the governing council of the organization for three-year terms.

Harold A. Whittaker, professor of public health engineering, was made vice president, and George O. Pierce, associate professor of public health engineering, was elected secretary of the association.

* * *

Veteran members of the medical profession in the neighborhood of Slayton joined recently with the local Civic and Commerce Association in sponsoring a dinner in honor of Dr. Leon A. Williams, of Slayton, who recently retired after a half century in medical practice in Murray County. Dinner was served in Wesley Hall and a program of interesting addresses and music by a male quartet was presented. Visiting doctors who paid tribute to Dr. Williams were Dr. Ludwig L. Sogge, of Windom, Dr. Herminus De Boer, of Edgerton, Dr. Byron O. Mork, of Worthington, Dr. Walter H. Valentine, of Tracy, and Dr. Sidney A. Slater, of Southwestern Sanatorium, at Worthington.

* * *

Dr. Ralph E. Wenzel has entered practice at Albert Lea with offices in the Albert Lea Medical and Surgical Center.

Dr. Wenzel, who is a 1938 graduate of Northwestern University Medical School, was in the U. S. Public

Health Service prior to entering military service. A member of the Coast Guard, he served as chief medical officer, captain of the Port of Los Angeles, and as assistant district medical officer in Honolulu. Later he was assigned to the Marine Hospital in Chicago. Since his separation from service he has been engaged in special study in obstetrics at the University of Iowa Medical School.

* * *

Headquarters, Fifth Army, has announced the promotion of Maxwell M. Barr, 1035 N. Washburn, Minneapolis, to the rank of captain, on December 19. Captain Barr was one of four medical officers who were promoted here.

Captain Barr received his medical degree at the University of Minnesota and was employed at the Mayo Clinic as an obstetrician prior to his entry into the armed services. He was commissioned in July, 1945, and attended an Army Specialized Training Program school before coming to the station hospital at Camp McCoy. His present duties are those of Receiving and Disposition Officer at the McCoy hospital.

* * *

The following Minnesota surgeons were received into fellowship in the American College of Surgeons on December 20, 1946, during the Clinical Congress held in Cleveland: David P. Anderson, Jr., Austin; William H. Bickel, Rochester; Everett B. Coulter, Minneapolis; Earl H. Dunlap, Minneapolis; Reinhold M. Ericson, Minneapolis; George T. R. Fahlund, Rochester; Fred Z. Havens, Rochester; Eugene M. Kasper, Saint Paul; Rochfort W. Kearney, Mankato; Paul C. Kiernan, Rochester; Howard H. Lander, Rochester; Paul N. Larson, Minneapolis; Donovan L. McCain, Saint Paul; John R. Paine, Minneapolis; Wesley G. Schaefer, Minneapolis; Anthony J. Spang, Duluth.

* * *

Dr. Kenneth A. Peterson has opened offices for the practice of medicine and surgery at Marshall in association with Dr. Frank D. Gray.

Dr. Peterson, who is the son of Dr. Roy A. Peterson, of Vesta, graduated from the University of Minnesota Medical School. He interned at the Minneapolis General Hospital and was resident physician at the Midway Hospital for two years prior to entering military service.

His army assignments included Northington General Hospital in Tuscalusa, Alabama, where he was engaged in neurosurgical, orthopedic and plastic surgery. Just prior to his separation from service he was at the Regional Hospital at Ft. McClellan, Alabama, where he was chief of the outpatient department.

* * *

Dr. Lawrence M. Randall was elected president of the staff of the Mayo Clinic at the annual staff dinner and meeting held at the Rochester Golf and Country Club, on November 18.

Dr. Edward N. Cook is the new secretary, Dr. John D. Camp was made first counselor and Dr. Monte C. Piper, second counselor.

Eleven physicians who have attained the rating of emeritus staff members at the Clinic were honored with testimonial booklets and gifts from the staff. Some of

them had been retired within recent months. These physicians were Dr. Samuel Amberg, Dr. William F. Braasch, Dr. H. Milton Conner, Dr. John L. Crenshaw, Dr. Herbert Z. Giffin, Dr. John H. Rosenow, Dr. Christopher Graham, Dr. Willis S. Lemon, Dr. Archibald H. Logan, Dr. Albert Miller and Dr. Charles G. Sutherland.

* * *

Six states were represented at the North Central Medical Conference held in Saint Paul in November. An address on rural medical care was given by Dr. L. W. Larson, of Bismarck, who is secretary of the North Dakota Medical Association. Pointing out that the two major phases of rural medical care are availability and cost, Dr. Larson stated that young physicians are being encouraged to locate in rural areas where the need is greatest, but added that farm people "must be able to offer a doctor a decent living wage, opportunity for advancement, facilities with which he can practice modern medicine and a desirable town in which to live."

HOSPITAL NEWS

Alvin Langehaug has been appointed superintendent of Fairview Hospital in Minneapolis, effective January 1. Mr. Langehaug comes from Chicago where he has been superintendent of a 180-bed Norwegian-American Hospital. He is a graduate of St. Olaf College and was a school superintendent in Minnesota from 1926 to 1937. He entered military service in 1943 and was discharged in 1945, as captain in the Army Medical Administrative Corps.

At one time Mr. Langehaug was superintendent of the Lutheran Hospital at Fort Dodge, Iowa, for six years. He is a past president of the Iowa Hospital Association, a member of the American Hospital Association and of the American College of Hospital Administrators.

* * *

Announcement has been made by the Board of Directors of Asbury Hospital, Minneapolis, of the election of Dr. Henry E. Hoffert as president of the staff. Other officers selected at the same time were Dr. Alfred N. Bessesen, vice president; Dr. Paul J. Preston, secretary and treasurer; and Dr. R. R. Cranmer, member of the advisory board. Holdover members of the board are Dr. Ernest R. Anderson, Dr. Thomas A. Peppard, and Dr. Leonard K. Buzzelle.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

THE CHEST—A Handbook of Roentgen Diagnosis. Leo G. Rigler, M.D., Professor and Chief, Department of Radiology, University of Minnesota. 352 pages. 338 illus. Price $6.50. Chicago: Year Book Publishers, Inc., 1946.

As might be expected by those who are familiar with Dr. Leo Rigler's teachings and previous writings, his new book on "The Chest" is a particularly outstanding work. The book is one of a series of handbooks of Roentgen Diagnoses published by the Year Book Publishers, Inc., of Chicago. Probably its greatest virtue is the number and brilliance of the reproductions and the exacting clarity and ease of correlation of the accompanying descriptions. The normal and normal variations, as well as the pathological, are adequately presented—a feature of real value to the student and occasional radiographer.

The entire field of abnormal chest roentgenology is remarkably well presented in the section on pathologic conditions. The amount of factual information presented, together with the wide variety of subjects covered, is, for a book of this size, most unusual. Most certainly the general coverage is such that it well provides "a foundation of knowledge and a guide for the analysis of any roentgenograms of the chest." This book will find wide usage as a constant reference for radiologists and as a source of fundamental information for students and practitioners. It far outdistances anything yet published in the field of chest roentgenology. It is a good reflection of a dynamic and brilliant teacher of Radiology—Leo Rigler!

C. N. Borman, M.D.

NATIONAL FORMULARY VIII. 888 pages. Price, $7.50. Eastin, Pa.; Mack Publishing Co., 1946.

The eighth edition of this standard work is now available. Published by the American Pharmaceutical Association, it provides official specifications for many widely used drugs not included in the U. S. Pharmacopoeia. Some 188 new admissions appear in the new issue. As new standards and formulas are devised, they will be made known through interim revisions or supplements. The new N. F. VIII becomes official April 1, 1947.

Delegates Hear Pleas

(Continued from Page 76)

licensure board, it was reported. The delegates approved Dr. Hedin's motion that two members of the present board of nurse examiners, one rural hospital administrator and one representative each from the medical profession and the practical nurses group should compose this board to have jurisdiction over all matters pertaining to the practical nurse.

In addition to approving the establishment of twenty one-year practical nurse training schools, the delegates also voted their approval of increasing the present three-year nurse training schools by ten.

Cognizance is being taken of this plea from the medical profession for remedial measures in the nursing field. Just recently the Board of Regents approved the establishment of a one-year course for practical nurses in connection with the School of Nursing at the University of Minnesota. Doubtless many hospitals throughout the state will take similar action as soon as the courses can be established.

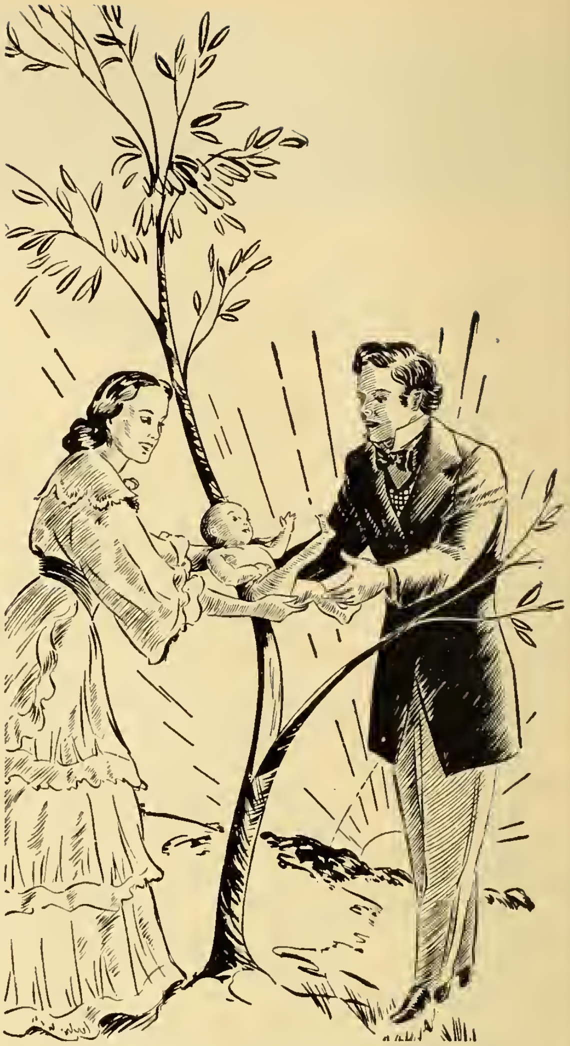
Old Way . . .

CURING RICKETS in the CLEFT of an ASH TREE

FOR many centuries,—and apparently down to the present time, even in this country—ricketic children have been passed through a cleft ash tree to cure them of their rickets, and thenceforth a sympathetic relationship was supposed to exist between them and the tree.

Frazer* states that the ordinary mode of effecting the cure is to split a young ash sapling longitudinally for a few feet and pass the child, naked, either three times or three times three through the fissure at sunrise. In the West of England, it is said the passage must be "against the sun." As soon as the ceremony is performed, the tree is bound tightly up and the fissure plastered over with mud or clay. The belief is that just as the cleft in the tree will be healed, so the child's body will be healed, but that if the rift in the tree remains open, the deformity in the child will remain, too, and if the tree were to die, the death of the child would surely follow.



It is ironical that the practice of attempting to cure rickets by holding the child in the cleft of an ash tree was associated with the rising of the sun, the light of which we now know is in itself one of Nature's specifics.

New Way . . .

Preventing and Curing Rickets *with* OLEUM PERCOMORPHUM

NOWADAYS, the physician has at his command, Mead's Oleum Percomorphum, a Council-Accepted vitamin D product which actually prevents and cures rickets, when given in proper dosage.

Like other specifics for other diseases, larger dosage may be required for extreme cases. It is safe to say that when used in the indicated dosage, Mead's Oleum Percomorphum is a specific in almost all cases of rickets, regardless of degree and duration. Mead's Oleum Percomorphum because of its high vitamins A and D content is also useful in deficiency conditions such as tetany, osteomalacia and xerophthalmia.

* * *

COUNCIL-ACCEPTED

Oleum Percomorphum With Other Fish-Liver Oils and Viosterol. Contains 60,000 vitamin A units and 8,500 vitamin D units per gram and is supplied in 10 c.c. and 50 c.c. bottles; and in bottles containing 50 and 250 capsules.

THIS INFORMATIVE COMPENDIUM ON A TIMELY SUBJECT

PHYSICIANS are invited to use the appended coupon to request a complimentary copy of the new brochure "Nutrition As A Therapeutic Factor." In a terse, straightforward manner, this compendium of current thought presents the remarkable strides made during the last decade in the use of nutritional factors as therapeutic weapons. The presentation concisely outlines present aspects of nutritional therapy providing information and data valuable in everyday practice. The applicability of the various nutrients in the treatment of disease is presented, adding to the practical utility of the brochure. The Wander Company, 360 North Michigan Ave., Chicago 1, Illinois.

THE WANDER COMPANY, 360 N. MICHIGAN AVENUE, CHICAGO 1, ILLINOIS

TROUBLE!

▶ THE CUTE LITTLE BABY he helped deliver back in 1925 is now suing him for $5,000 because of an instrument scar.

▶ His state's 2-year statute of limitations is no help, for the 2 years didn't start 'til the "baby" was 21.

▶ Yet this doctor would lose neither time, money, sleep nor reputation if protected by our policy and service (as are thousands of other doctors, for about the cost of a good pair of shoes).

▶ For the world's largest legal staff of malpractice experts already would be cutting through mountains of conflicting court decisions and anticipating schemes that might otherwise "prove" his guilt.

▶ All cost of defense against disgruntled patients, even through the court of last appeal (including fee of attorney whom *you* help choose), is paid by us. If not acquitted, we also pay the judgment, as provided in our policy.

When life is measured in days

Not years, nor months, but days measure the life of a new-born infant. And during the first 30 days when infant mortality is at its highest, every effort must be made to minimize the hazards to life. At this critical time, the right start on the right feeding can be of vital importance.

'Dexin' has proved an excellent "first carbohydrate." Because of its high dextrin content, it (1) resists fermentation by the usual intestinal organisms; (2) tends to hold gas formation, distention and diarrhea to a minimum, and (3) promotes the formation of soft, flocculent, easily digested curds.

Readily prepared in hot or cold milk, 'Dexin' brand High Dextrin Carbohydrate is palatable but not too sweet. 'Dexin' *does* make a difference.

'Dexin' **HIGH DEXTRIN CARBOHYDRATE**
BRAND

Composition—Dextrins 75% • Maltose 24% • Mineral Ash 0.25% • Moisture 0.75% • Available carbohydrate 99% • 115 calories per ounce • 6 level packed tablespoonfuls equal 1 ounce • Containers of twelve ounces and three pounds • Accepted by the Council on Foods and Nutrition, American Medical Association.

EXPERIENCE IS THE BEST TEACHER!

NEWS ITEM, 1944

Cigarette shortage spreads ...Counters jammed... Millions try different brands —any brand they can get.

According to a recent Nationwide survey:

MORE DOCTORS SMOKE CAMELS

than any other cigarette

Doctors too smoke for pleasure. Their taste recognizes and appreciates full, rich flavor and cool mildness just as yours does. And when three independent research organizations asked 113,597 doctors—What cigarette do you smoke, Doctor?—*the brand named most was Camel!*

EXPERIENCE TAUGHT MILLIONS

the Differences in Cigarette Quality

...and now the demand for Camels—always great—is greater than ever in history.

DURING the war shortage of cigarettes ... that's when your "T-Zone" was really working overtime.

That's when your Taste said, "I like this brand"...or..."That brand doesn't suit me." That's when your Throat said, "This cigarette agrees with me"...or..."That one doesn't."

That's when millions of people found that their "T-Zone" gave a happy okay to the rich, full flavor and the cool mildness of Camel's superb blend of choice tobaccos.

And today more people are asking for Camels than ever before in history. But, no matter how great the demand:

We do not tamper with Camel quality. We use only choice tobaccos, properly aged, and blended in the time-honored Camel way!

CARTOSE
REG. U.S. PAT. OFF.
A Mixed Carbohydrate for Supplementing Milk
FOR INFANT FEEDING
As Directed by Physician
DEXTRINS - MALTOSE - DEXTROSE
hydrolyzed from pure starch providing
—spaced absorption, uniform composition
—freedom from irritating impurities
—a hermetic seal of high vacuum
Two tablespoonfuls equal 1 fl. oz.
120 calories per fl. oz.
MADE FOR
H. W. KINNEY & SONS, INC.
Kinney
COLUMBUS, INDIANA, U.S.A.

EASE AND ECONOMY OF USE

Specification of CARTOSE* as the mixed carbohydrate for infant feeding formulas provides ease and economy of use. The liquid form of this milk modifier permits rapid, accurate measurement, thereby avoiding waste.

Double protection against contamination is afforded by: (1) the narrow neck of the bottle, preventing spoon insertion, and (2) the press-on cap, assuring effective resealing.

CARTOSE supplies nonfermentable dextrins in association with maltose and dextrose . . . a combination providing spaced absorption that minimizes gastrointestinal distress due to fermentation.

Available in clear glass bottles containing 1 pt. • Two tablespoonfuls (1 fl. oz.) provide 120 calories.

Smooth labor

Demerol, the potent, synthetic analgesic, spasmolytic and sedative, relieves labor pains promptly and effectively without danger to mother and child. There is no weakening of uterine contractions, lengthening of labor, or postpartum complication due to the drug. Bad effects on the newborn are practically nil: no respiratory depression or asphyxia from too much analgesia of the mother. Simplicity of administration is another commendable feature. Warning: May be habit forming.

Ampuls (2 cc., 100 mg.); vials (30 cc., 50 mg./cc.). Narcotic blank required.

a photogenic contrast medium

PRIODAX, a superior contrast medium for oral cholecystography, is photogenic — taking a "good picture" consistently. Because it is rarely lost by vomiting or diarrhea from the gastrointestinal tract, a maximum is concentrated in the gallbladder to produce a clear, sharp shadow. "Retakes" are therefore reduced to a minimum, while little or no residual contrast substance appears in the colon to obscure accurate diagnosis.

PRIODAX

(brand of iodoalphionic acid)

PRIODAX, beta-(4-hydroxy-3, 5-diiodophenyl)-alpha-phenyl-propionic acid, is available in 0.5 Gm. tablets in economy boxes of 100 envelopes and in boxes of 1, 5 and 25 envelopes. Each envelope contains 6 easily swallowed tablets constituting the usual dose. Directions for the patient are enclosed with each package.

Trade-Mark PRIODAX—Reg. U. S. Pat. Off.

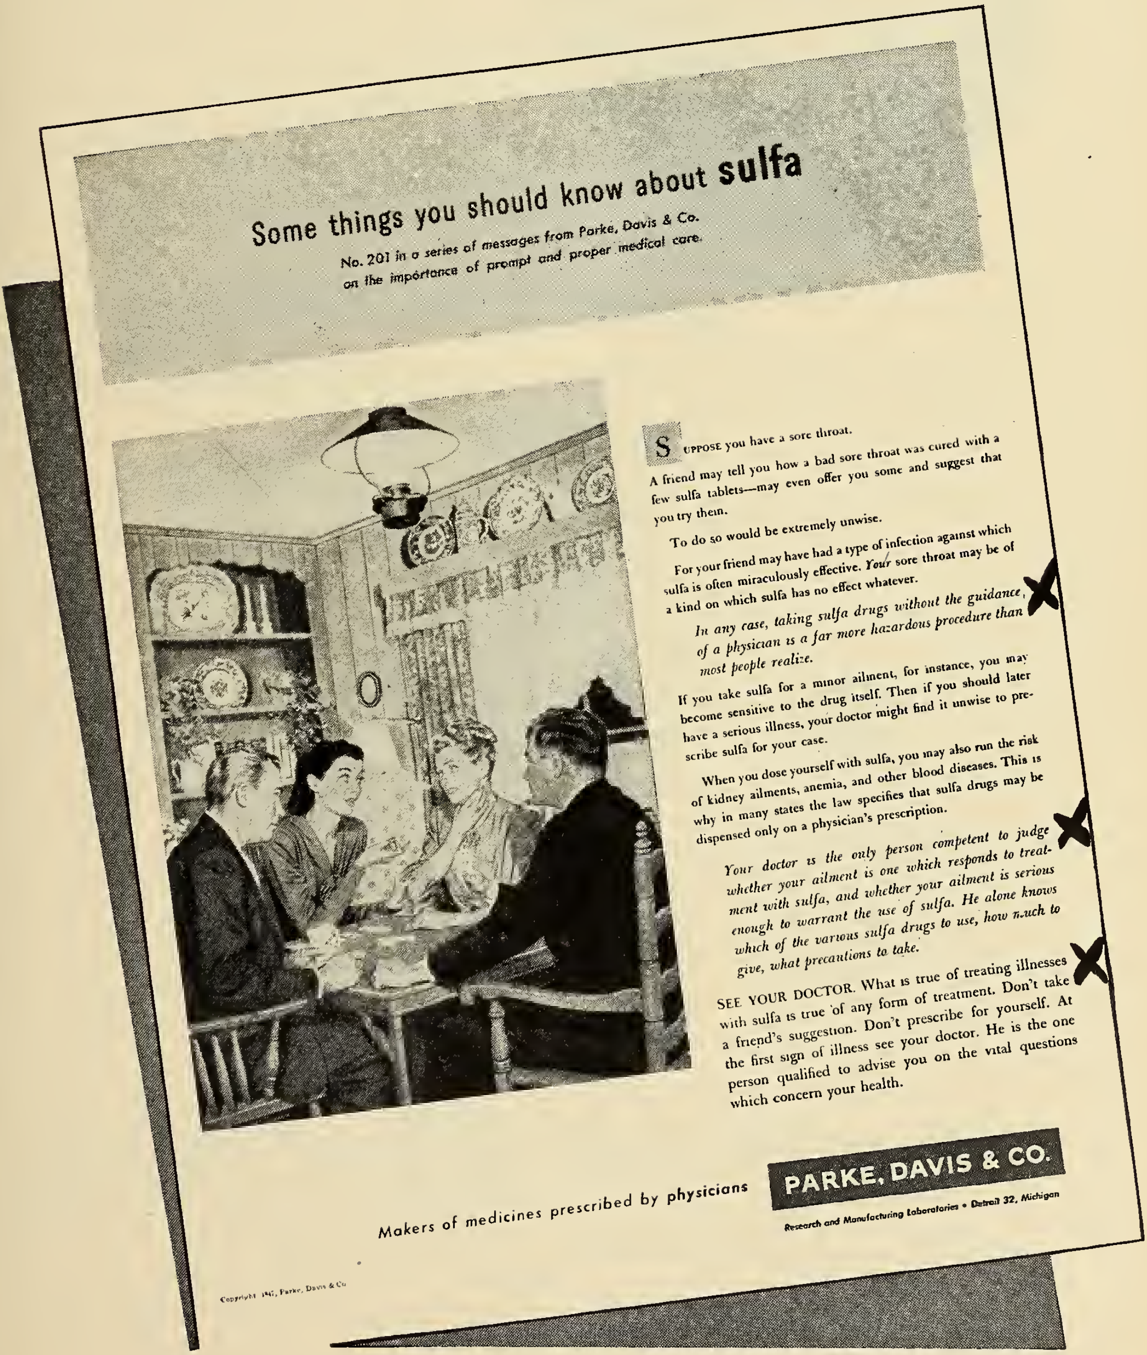
Educating the public to "see your doctor"

This is No. 201 in the Parke-Davis series of messages published in the interest of the medical profession. Appearing in color in LIFE and other leading magazines, it will reach an audience of over 23 million people.



Some things you should know about **sulfa**

No. 201 in a series of messages from Parke, Davis & Co.
on the importance of prompt and proper medical care.

Suppose you have a sore throat.

A friend may tell you how a bad sore throat was cured with a few sulfa tablets—may even offer you some and suggest that you try them.

To do so would be extremely unwise.

For your friend may have had a type of infection against which sulfa is often miraculously effective. Your sore throat may be of a kind on which sulfa has no effect whatever.

In any case, taking sulfa drugs without the guidance of a physician is a far more hazardous procedure than most people realize.

If you take sulfa for a minor ailment, for instance, you may become sensitive to the drug itself. Then if you should later have a serious illness, your doctor might find it unwise to prescribe sulfa for your case.

When you dose yourself with sulfa, you may also run the risk of kidney ailments, anemia, and other blood diseases. This is why in many states the law specifies that sulfa drugs may be dispensed only on a physician's prescription.

Your doctor is the only person competent to judge whether your ailment is one which responds to treatment with sulfa, and whether your ailment is serious enough to warrant the use of sulfa. He alone knows which of the various sulfa drugs to use, how much to give, what precautions to take.

SEE YOUR DOCTOR. What is true of treating illnesses with sulfa is true of any form of treatment. Don't take a friend's suggestion. Don't prescribe for yourself. At the first sign of illness see your doctor. He is the one person qualified to advise you on the vital questions which concern your health.

New Strength

FOR THE FAILING MYOCARDIUM . . .

and in a Matter of Hours

Six tablets of Digitaline Nativelle (0.2 mg. each) usually enable the heart in the throes of decompensation to cope again with the circulatory demands. This total oral digitalizing dose, taken at one time, effects complete digitalization in 6 to 8 hours.

The action of Digitaline Nativelle, the original digitoxin, is virtually free from locally induced nausea and vomiting, yet produces all the desirable cardiotonic influence of whole leaf digitalis from which it is extracted. Initial maintenance dose, 0.1 mg. daily; in some patients 0.05 mg. suffices, in others, 0.2 mg. daily may be required.

Physicians are requested to send for a complimentary copy of the brochure "Management of the Failing Heart" and a clinical sample of Digitaline Nativelle sufficient to digitalize one patient.

FORMULAC FOR GENERAL INFANT FEEDING

Formulac Infant Food provides a balanced and flexible formula basis for general infant feeding — both in normal and difficult diet cases.

Developed by E. V. McCollum, Formulac is a concentrated milk in liquid form, fortified with all vitamins known to be necessary for proper infant nutrition. No supplementary vitamin administration is necessary with Formulac. The Vitamin C content is stabilized, assuring greater safety.

The only carbohydrate in Formulac is the natural lactose found in cow's milk—no other carbohydrate has been added. This permits you to prescribe both the amount and the type of carbohydrate supplementation required.

Formulac is promoted ethically, to the medical profession only. Clinical testing has proved it satisfactory in promoting normal infant growth and development. On sale in grocery and drug stores throughout the country, Formulac is priced within range of even modest incomes.

Furunculosis .... second in the series: "FACIAL EXPRESSIONS OF SICKNESS"

From a practical standpoint, the use of penicillin orally should be limited to the infections in which low doses of parenteral penicillin have proved adequate; to prophylaxis; and to the convalescent stages of such acute infections as furunculosis. Here, when the crisis is past and the fever receded, the use of two tablets (100,000 units) every hour or six tablets (300,000 units) at three hour intervals, day and night, for 48 hours is a tested safeguard against relapse. For such prophylaxis, tablets of calcium penicillin, 50,000 units each, are available in bottles of 12.

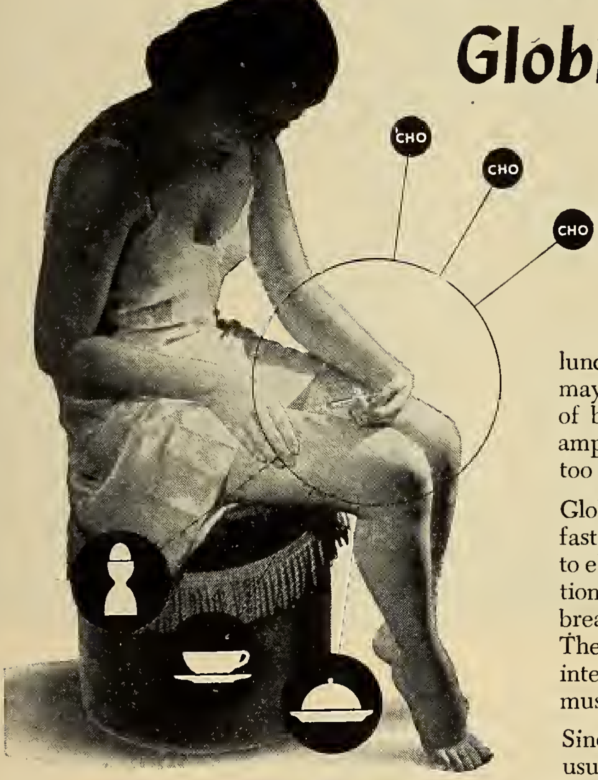
Diabetes, diet and Globin Insulin . . .



THE ADVANTAGES of one-injection control of diabetes can, through adjustment of diet and dosage, be made available to the majority of patients requiring insulin. In view of the convenience and freedom afforded by the unique intermediate action of 'Wellcome' Globin Insulin with Zinc, the necessary adjustment is well worth while. Though not a complicated procedure, the regulation of carbohydrate balance warrants reiteration because of its importance:

SOME FACTS ABOUT DIETARY ADJUSTMENT: The distribution of carbohydrate in the meals must be adjusted in accord with the type of action exhibited by Globin Insulin, which is intermediate between regular and protamine zinc insulin. Proper carbohydrate distribution with proper insulin timing is essential; lack of balance may lead to poor control or to an erroneous impression of the characteristics of Globin Insulin.

A good carbohydrate distribution for the patient on Globin Insulin is to divide the total carbohydrate per day into 1/5 at breakfast, 2/5 at lunch and 2/5 at suppertime. This initial diet may be adjusted in accord with the indications of blood sugar levels and urinalyses. (For example, a low blood sugar before supper indicates too little carbohydrate for lunch or vice versa.)

Globin Insulin is ordinarily given before breakfast. Onset of action is usually sufficiently rapid to eliminate the need for a supplementary injection of regular insulin. However, the amount of breakfast carbohydrate should not be too large. The right amount, as well as the optimal time interval between the injection and breakfast, must of course be determined for each patient.

Since the maximum action of Globin Insulin usually occurs in the afternoon or early evening, hypoglycemia is sometimes noted at this time. As a guard against it, the carbohydrate content of the noon meal may be increased, or a midafternoon lunch provided. Thus the original distribution of 1/5, 2/5 and 2/5 might, for example, require adjustment to 2/10, 5/10 and 3/10 or to 2/10, 4/10, 1/10 and 3/10. Once the balance of carbohydrate intake and insulin timing has been established, the patient must be impressed with the importance of adhering to the regimen.

'Wellcome' Globin Insulin with Zinc is a clear solution, comparable to regular insulin in its freedom from allergenic properties. Available in 40 and 80 units per cc., vials of 10 cc. Accepted by the Council on Pharmacy and Chemistry, American Medical Association. Developed in The Wellcome Research Laboratories, Tuckahoe, New York. U.S. Patent No. 2,161,198. Most
DEPENDABLE
Method

The combined use of an occlusive diaphragm and vaginal jelly remains, in the published opinions of competent clinicians, the most dependable method of conception control.

Dickinson[1] has long held that the use of jellies alone cannot be relied upon for complete protection. It is noteworthy that in the series of patients studied by Eastman and Scott[2], an occlusive diaphragm was employed in conjunction with a spermicidal jelly for effective results. Warner[3], in a carefully controlled study of 500 patients, emphasized the value of a diaphragm.

In view of the preponderant clinical evidence in its favor, we suggest that physicians will afford their patients a high degree of protection by prescribing the diaphragm and jelly technique.

You assure quality when you specify a product bearing the "RAMSES"* trademark.

Dietary Dub!

His work is performed with infinite care . . . But he chooses his meals on whim. He eats only the foods he likes—a choice of notably limited range. The inevitable result is a further increase in the ranks of the self-made victims of borderline vitamin deficiency. You know many of them: the ignorant and indifferent, patients "too busy" to eat properly, those on self-imposed and badly balanced reducing diets, excessive smokers, alcoholics, and food faddists, to name but a few. First thought in such cases is dietary reform, of course. But this is often more easily advised than accomplished. Because of this, an ever-growing number of physicians prescribe a vitamin supplement in every case of deficiency. If you're one of these physicians—or if you prescribe vitamins only rarely—consider the advantages of specifying an *Abbott* vitamin product: Quality—Certainty of potency—A line which includes a product for almost every vitamin need—And easy availability through good pharmacies everywhere. ABBOTT LABORATORIES, North Chicago, Illinois.

THE USE OF INSULIN MIXTURES

RANDALL G. SPRAGUE, M.D., and LAURENTIUS O. UNDERDAHL, M.D.
Rochester, Minnesota

DURING the first fifteen years following the discovery of insulin in 1921, there was a growing appreciation by physicians interested in the treatment of diabetes of the shortcomings of soluble insulin. The principal of these shortcomings are related to its brief, intense action. The results of this inefficient type of action are the necessity for multiple injections each day in the treatment of severe diabetes, the danger of insulin reactions due to precipitous falls of the blood sugar level, and the lapses of control of severe diabetes in the interval between the waning of action of one dose and the injection of the next.

With the introduction of protamine insulin in 1936, and of protamine zinc insulin shortly afterward, the possibility of modifying insulin in the direction of a more prolonged action of lesser intensity was realized. At that time it was hoped that in many of the cases in which multiple injections daily of soluble insulin had been required, the diabetes would remain under satisfactory control with a single injection daily of protamine zinc insulin. Unfortunately, in many cases this hope has not been realized, for reasons which now seem obvious. Protamine zinc insulin does not have sufficient intensity of action to prevent excessive glycosuria following the ingestion of food in cases of severe diabetes, while its continuing action during the fasting hours of the night may result in hypoglycemic reactions while the patient is asleep. Among all the cases in which diabetes is severe enough to require insulin, only the relatively mild ones (usually those requiring 20 units or less daily) are satisfactorily regulated with a single dose of protamine zinc insulin alone with assurance that nocturnal reactions will be avoided.

Thus, it soon became apparent that some compromise between the short, intense action of soluble insulin and the prolonged, weak action of protamine zinc insulin would have greater therapeutic usefulness than either of these two insulins alone. Treatment with both types of insulin injected separately has been widely employed as a means of achieving this compromise, but this method is objectionable because multiple injections are required. Lawrence[3] of London was the first to suggest treating diabetes with a single daily injection of soluble and protamine zinc insulin mixed in one syringe. Following his suggestion, the Section on Metabolism Therapy of the Mayo Clinic has been using such mixtures since 1938 in the treatment of many diabetic patients. Day-by-day clinical observation and controlled clinical investigation by ourselves and others have taught us much about the mode of action and the clinical applicability of such mixtures. The most important single lesson that has been learned from observation of patients is that mixtures containing two or three times as much soluble insulin as protamine zinc insulin are the most suitable for the treatment of diabetes which is severe enough to require the use of mixtures. This observation is corroborated by several experimental studies, notably those of Colwell and his colleagues.[2] The latter investigators showed that definite intermediate effects, in terms of promptness, intensity and duration, are not obtained un-

---

Read at the meeting of the Northern Minnesota Medical Assocaition, Crookston, Minnesota, August 24, 1946.

til the mixture contains at least as much soluble insulin as protamine zinc insulin. By increasing the proportion of soluble insulin further, any desired effect intermediate between those of the two kinds of insulin alone can be obtained.

Colwell[1] showed further that when excess soluble insulin is added to protamine zinc insulin in ratios as high as 4:1, virtually no soluble insulin remains in the supernatant, and the mixture has a monophasic action on injection. In simple terms, this means that protamine has a tremendous capacity to combine with insulin, with the result that the insulin in the commonly employed mixtures is in a single complex rather than two (rapid-acting and slow-acting) compounds. Thus, it is not technically correct to speak of the quick action of the regular insulin and the slow action of the protamine zinc insulin in a mixture. The mixture is in reality a single compound which is different from either of the component types of insulin in that the protamine is more saturated with insulin than it is in commercial protamine zinc insuln. The result of such saturaton of protamine is that insulin is released at a more rapid rate than from standard protamine zinc insulin.

Aims of Treatment

Let us digress for a moment to consider the aims of treatment of diabetes with particular reference to the physiologic problem involved in the use of insulin in the treatment of diabetes. The aim of treatment can be simply stated as being the maintenance of health and vigor for a normal span of life. This implies avoidance of acute complications, such as insulin reactions and ketosis, as well as the chronic degenerative complications of the disease, such as retinopathy, neuropathy and intercapillary glomerulosclerosis. At the present time it seems that the treatment which is most likely to achieve the desired end is that which maintains optimal nutrition and reduces the excretion of glucose in the urine to the lowest possible level consistent with a livable program and the avoidance of insulin reactions. Precise control of the level of the blood sugar, which in some cases can be achieved only by frequent injections of insulin and bizarre adjustments of the diet, and in other cases cannot be achieved at all, probably offers no additional advantage. Evidence is accumulating that even the most precise control of diabetes will not always prevent the development of degenerative complications.

The theoretical aim in administering insulin to the patient who has diabetes is to supplement his own endogenous production of insulin in such a way as to imitate as closely as possible the secretion of insulin by the normal pancreas. While there is much that is not understood about the regulation of insulin secretion, a reasonable physiologic hypothesis provides useful guidance in the administration of insulin to patients. Indirect evidence suggests that there are two types of secretion: (1) a continuous slow secretion during fasting, which serves to prevent excessive catabolism of body protein and fat and to maintain the blood sugar at a normal level against the various factors which tend to elevate it, and (2) an augmented secretion following the ingestion of food, which in most persons prevents the excretion of more than small amounts of glucose in the urine. An exact imitation of these mechanisms is impossible to attain, but by skillful employment of quick and slow acting insulins the physician is usually able to achieve a reasonably satisfactory approximation of the normal processes. Obviously, in the treatment of severe diabetes in which most, if not all, of the body's requirement for insulin must be injected, the normal mechanisms of insulin secretion will be better imitated by a type of insulin which provides both rapid and slow actions than they would be by an insulin which provides only one of these.

The principal indication, then, for the use of mixtures of protamine zinc insulin and regular insulin is diabetes of such severity that glycosuria is not adequately controlled and insulin reactions are not avoided by the use of a single morning dose of protamine zinc insulin of moderate size. It would be extravagant to claim that such mixtures solve all the therapeutic problems of severe diabetes, for there still remains a small group of cases in which insulin reactions and poor control of glycosuria continue to be major problems.

Clinical Use of Mixtures

The use of extemporaneous rather than fixed mixtures of the two types of insulin provides necessary flexibility of quick and slow action.* The combined dose is administered in one syringe in the morning before breakfast. As previously stated, mixtures containing two to three times as much soluble insulin as protamine zinc insulin have proved to be the most effective in the treatment of severe diabetes. Of 100 patients who were recently treated with mixtures, the ratio of soluble to protamine zinc insulin was from 2:1 to 3:1, inclusive, in eighty-seven (Table I). The more severe the diabetes, or the higher the carbohydrate content of the diet, the more likely is the ratio to be in the neighborhood of 3:1 rather than 2:1. The strong effects of the mixture prevent excessive glycosuria during the day when food is being ingested, and the prolonged slow effects prevent escape from control overnight.

---

*The use of extemporaneous mixtures of protamine zinc insulin and soluble insulin in one syringe calls for precautions to prevent the introduction of one kind of insulin into the other bottle. An appropriate volume of air is first injected into the bottle of protamine zinc insulin and the needle is withdrawn without permitting any insulin to enter the syringe. Then the desired dose of soluble insulin is drawn into the syringe in the usual manner. After this the needle is again inserted into the bottle of protamine zinc insulin and the desired dose is allowed to flow into the syringe, overlying the soluble insulin which is already there. The two kinds of insulin are mixed by drawing a small bubble of air into the syringe, inverting the syringe several times and then expelling the bubble.

TABLE I. MIXTURES OF SOLUBLE AND PROTAMINE ZINC INSULIN IN 100 CASES OF DIABETES MELLITUS

Ratio of soluble to protamine zinc insulin	Cases
1:1 to 1.5:1	5
1.5+:1 to 2−:1	5
2:1 to 2.5:1	62
2.5+:1 to 3:1	25
3+:1 to 3.5:1	2
3.5+:1 to 4:1	1

As pointed out by Colwell,[1] problems of insulin therapy would be simplified by the marketing of a modified insulin having an action like that of a 2:1 mixture of soluble and protamine zinc insulin, in place of the commercial protamine zinc insulin which is now available. Such an insulin would obviate the need for extemporaneous modification in many cases, as it would fill the needs of all the patients who are now successfully treated with protamine zinc insulin alone, as well as of the majority of the patients who are now treated with mixtures. In the few cases in which higher ratios of soluble to protamine zinc insulin are required, supplementation with additional soluble insulin could be readily accomplished in accordance with the needs of the individual patient.

Patients whose diabetes is eventually found to be controllable with mixtures in which the ratio of soluble to protamine zinc insulin is 1:1 or less, usually have relatively mild diabetes, which fares equally well with a single small morning dose of protamine zinc insulin. The use of various kinds of insulin in diabetes of different degrees of severity has been discussed by Wilder[5] and by Sprague.[4]

Adjustment of the Dose

The size of the initial mixed dose in new cases depends on clinical judgment and an estimate of the fundamental severity of the diabetes. For example, if the patient is an adult whose diabetes is anticipated to be basically mild, even though the patient may present himself with fairly intense glycosuria, the starting dose may be of the order of 6 units of protamine zinc insulin and 12 units of soluble insulin. If the diabetes is of greater severity, as is the rule among children, adolescents and young adults, the dose may be of the order of 12 units of protamine zinc insulin and 24 units or more of soluble insulin. Rarely need the total initial dose exceed 60 units. Small children can be expected to respond to smaller doses than young adults. In the absence of ketonuria, caution should be exercised in increasing the dose during the first few days of treatment, for the full effects of the starting dose may not be apparent for several days.

Whatever the initial dose of insulin, subsequent adjustments are made on the basis of frequent tests of the urine for sugar. Until a satisfactory balance is established, the urine is tested four times daily. Once reasonable control has been achieved, further adjustment of the doses of the two kinds of insulin can be made on the basis of two daily tests: (1) The test of a fresh specimen† voided in the morning before breakfast is a satisfactory criterion of the adequacy of the dose of protamine zinc insulin. The dose is adjusted so that there will be no nocturnal insulin reactions and no more than traces of sugar in the morning specimen. (2) The test of a fresh specimen voided late in the afternoon before supper serves as an index of the adequacy of the dose of soluble insulin. The aim is to adjust this dose so that there will be few or no insulin reactions during the day and no more than traces of sugar in this specimen.

When it is necessary to increase or decrease the dose of insulin, the magnitude of the change should depend on several factors. As a rule, the larger the dose, the larger the change should be. Since most mixed doses will contain approximately twice as much soluble insulin as protamine zinc insulin, the magnitude of change of the two kinds of insulin is kept in about the same proportion

---

†Only if the urine has been recently secreted by the kidneys will the urine tests provide accurate information about the state of the diabetes at the time when the test is made. To this end, the patient is instructed to empty the bladder about thirty minutes before collecting the specimen for testing.

For example, the soluble insulin may be changed 4 units at a time, and the protamine zinc insulin 2 units at a time. Very large doses of soluble insulin may be raised or lowered 6 or 8 or more units at a time. Some small children, and a few adults, are so sensitive to small changes that alterations in steps of more than 2 units may be inadvisable.

Any rules for adjustment of doses must be modified to suit the vagaries of the individual case. In some cases of severe diabetes, for example, once preliminary regulation has been completed and tolerance has become stabilized, it may be wise not to alter the doses of the two kinds of insulin in spite of occasional intense glycosuria or mild insulin reactions, since such transient fluctuations may be due to factors other than insulin. Among these factors are emotional disturbances, irregularities of rate of absorption of insulin from different sites of injection, and variations of food intake and physical activity. A sound principle in such cases is to find a dose of insulin which provides adequate control on most days and adhere to it until there is good reason to make a change.

Most physicians have had experience with cases of severe diabetes in which glycosuria is not satisfactorily controlled and insulin reactions are not avoided throughout the twenty-four hours by the use of a single mixed dose of protamine zinc insulin and soluble insulin. Control in such cases is sometimes improved by the addition of a small dose of soluble insulin before supper. Usually this dose need not exceed 10 or 12 units. Adjustments of dose are then made chiefly in the soluble insulin taken in the morning and evening, for the dose of protamine zinc insulin can usually be kept small and requires little or no alteration. The afternoon test of the urine, and insulin reactions occurring during the day, are the guides for adjustment of the morning dose of soluble insulin. The evening dose of soluble insulin is adjusted on the basis of the morning test of the urine and nocturnal reactions.

Summary

Mixtures of protamine zinc insulin and soluble insulin in proper proportions provide both quick, intense action and slow, prolonged action. They are more effective than either of the two component insulins alone in most cases of moderately severe to severe diabetes. A proper proportion in most instances is between 2 and 3 units of soluble insulin to 1 unit of protamine zinc insulin.

Such mixtures attain their greatest effectiveness in those cases of moderately severe diabetes which have long been recognized as being reasonably easy to treat by a variety of therapeutic programs involving multiple doses of soluble insulin. They do not solve all the problems of insulin therapy in patients who have severe, "brittle" diabetes of the type which has always been difficult to control with any program of treatment.

Extemporaneous mixtures have the advantage of flexibility, which makes them adaptable to a variety of cases. Such flexibility is desirable as it has not been possible thus far to produce any single modification of insulin which will fill the needs of all cases of diabetes. However, a modified insulin having an action like that of a 2:1 mixture of soluble and protamine zinc insulin could be used without modification in many more cases than the standard protamine zinc insulin which is now available. It could be further modified by the extemporaneous addition of more soluble insulin when necessary.

ATOMIC ENERGY—ITS MEDICAL APPLICATION

A problem of extraordinary importance is before the Council on Physical Medicine and the Council on Industrial Health of the American Medical Association, namely, atomic energy and its medical applications.

At a joint meeting of the two Councils, specialists on roentgen rays, radium and atomic energy discussed a long-range program for considering the products, the problems and the means of disseminating information.

The Council on Industrial Health decided to sponsor articles on the dangers associated with the manufacture of radioactive material. The Council on Physical Medicine voted to prepare articles for publication in *The Journal of the American Medical Association* on the therapeutic and diagnostic uses of radioactive isotopes.

THE PRESENT SOUTHERN MINNESOTA MEDICAL ASSOCIATION

Its Antecedents, Purposes and Character

CARLE B. McKAIG, M.D.
Pine Island, Minnesota

IT is said that excessive preoccupation with the past is an indication of senility and, no doubt, this is true. Age dreams of the past while youth anticipates the future with eagerness. However, I believe that a reasonable pride in our history and tradition is commendable, and our organization has a history of which we may well be proud.

The older members of the association are familiar with its history. There are, however, those who have become members since the history was last reviewed. This was in 1935, when Dr. M. C. Piper presented an excellent historical sketch. It is for the newer members particularly that I present this review.

The present Southern Minnesota Medical Association was formed August 3, 1911, at Rochester. It was brought into being by merger of the Minnesota Valley Medical Association and the old Southern Minnesota Medical Association. The organization thus formed was given the name of the latter component association.

The Minnesota Valley Medical Association

The Minnesota Valley Medical Association, the older of the two components, was organized December 1, 1880, at Le Sueur Center. A preliminary meeting had been held the previous October in Le Sueur Center.

It is said that the plan for the organization originated with the physicians of Mankato. However, Dr. Otis Ayer, of Le Sueur Center, took the initiative to the extent of writing to a number of physicians, requesting their presence at the organizational meeting. The original plan specified that there were to be two meetings a year, one of which always was to be held in Mankato.

This organizational meeting was held sixty-six years ago. To correlate it with national events, let me point out that this was only fifteen years after the close of the Civil War. President Garfield was in office. The great Indian War of the Northwest was just over, and the country was still mourning those who had died at the Battle of the Little Big Horn, in 1876, just four years before. To correlate the organizational meeting with contemporary medical history, 1880 was the year in which Lord Lister introduced the use of catgut in surgery of the vascular system. Only thirteen years had passed since he had published his revolutionary paper, "On the Antiseptic Principle in the Practice of Surgery," which marked the beginning of modern surgery.

Medical education in the United States was in a chaotic state and momentous changes were taking place in medical knowledge and practice. The earnest men who formed the Minnesota Valley Medical Association truly appreciated the vital need for an organization which would further medical knowledge.

Transportation was an important factor and was necessarily by railroad. Hence, it was planned that the membership of the Minnesota Valley Medical Association be drawn, in a general way, from those communities which lay along the "Omaha Road," as one portion of the Chicago and Northwestern Railroad was called in those days. There were thirteen charter members but, by 1883, the members numbered forty-five. Dr. Otis Ayer was elected the first president. He had been surgeon to the Second Minnesota Regiment of Volunteers and he became president of the Minnesota State Medical Association in 1877. He died in 1889.

Dr. C. F. Merritt, of St. Peter, was first treasurer and continued to hold this office through the entire existence of the association, and also after its merger with the Southern Minnesota Medical Association, until his death in 1921.

At the time of the merger, in 1911, Dr. E. J. Davis, of Minnehaha, presented a brief historical sketch of the Minnesota Valley Medical Association. He recalled that the original programs had consisted entirely of reports of cases. Each member in turn described cases he had encountered in his practice since the last meeting and the entire membership then discussed each case. Later, the meetings came to assume a more formal character, with prepared papers and open discussion following.

Presidential Address, Southern Minnesota Medical Association, delivered at Faribault, Minnesota, September 9, 1946.

In the same sketch, Dr. Davis also pointed out that inasmuch as money was very scarce and hard to obtain in those days, no avoidable expense was incurred by the association. In this matter, the interests of the young physician were being considered particularly, as it was thought that he needed the association most and he had the least money to pay for its maintenance. It was thought that everything should be done to encourage his attendance. There were no banquets for this reason. The annual dues were 50 cents, with an extra assessment of 50 cents whenever the treasury was empty.

In 1880, wheat sold for 87 cents per bushel, but beef brought $3.66 per hundred weight, and pork $5.10 per hundred weight. This was the economic background against which the Minnesota Valley Medical Association was founded.

Members of the association were all pioneers; many were former army surgeons, and some had been Indian fighters. Their origins were largely in the East. Some were Europeans. They were truly representative of the original stock of the State of Minnesota. The association was the first district medical organization in the state.

The Old Southern Minnesota Medical Association

The second of the two original component societies, the Southern Minnesota Medical Association, was formed in Winona on July 26, 1892. Agitation for formation of this organization apparently had existed for a long time. For instance, Mrs. N. H. Guthrie, of the Mayo Clinic, while engaged in research on the history of medicine in Minnesota, discovered an item in the *Rochester City Post* for January 16, 1869. Therein it was reported that a communication had been received by the Olmsted County Medical Society, from Dr. Youmans, of Winona, advocating that the Olmsted County Medical Society, which had been formed only the previous year, be enlarged to include all Southern Minnesota.

At the first meeting of this old Southern Minnesota Medical Association, a program of five papers was presented. It was as follows:

Cerebrospinal meningitis—Dr. McGaughey, Winona

Less common forms of surgical tuberculosis—Dr. W. J. Mayo, Rochester

Endometritis—Dr. W. T. Adams, Elgin

Hypertrophic rhinitis—Dr. H. H. Witherstine, Rochester

Consideration of the knee jerk symptoms—Dr. R. M. Phelps, Rochester

The meetings rotated among Winona, Rochester and Owatonna, and were held annually.

One of the duties of the secretary was to canvass the members for papers to be presented at the annual meeting. Apparently the response was good because the papers presented were, for the most part, by the members themselves. I think our present membership might take a lesson from this and give a better response to the request of the program committee for papers. It is becoming increasingly difficult for the committee to obtain papers from the members. During the entire eighteen years of the existence of the old Southern Minnesota Medical Association, there were only two secretaries: Dr. Adams, of Elgin, and Dr. Witherstine, of Rochester.

The New Southern Minnesota Medical Association

The Minnesota Valley Medical Association and the old Southern Minnesota Medical Association existed side by side for eighteen years. There was considerable duplication of function and overlapping of territory. Many physicians were members of both. A merger of the two associations obviously was indicated and was effected, as has been said, on August 3, 1911, thirty-five years ago, at a meeting in Rochester. An entirely new society was formed but the name, Southern Minnesota Medical Association, was retained, as has been pointed out. This name was considered appropriate because the object of the organization was to serve the needs of members of the medical profession in the southern part of the state.

Dr. L. A. Fritche of New Ulm was the first president of the new society. Following the merger, the society grew rapidly. Programs became elaborate and meetings extremely well attended. Many national figures appeared on the programs. For instance, in 1914, the guest speakers included Dr. Bertram W. Sippy, Dr. Dean Lewis, Dr. Allen B. Kanavel, Dr. Oliver S. Ormsby, Dr. H. M. McClanahan, Dr. James S. Goetz, and Dr. Arthur D. Dunn.

In 1919 it was apparent to many members that the association had become too large and its pro-

GLOMUS TUMORS

Report of Two Cases

HENRY W. MEYERDING, M.D. and JAMES H. VARNEY, M.D.
Rochester, Minnesota

GLOMUS tumors may cause excruciating pain. Because of their rarity they may remain unrecognized for years. Recently we have operated on two patients who had glomus tumors of nine and sixteen years' duration, respectively. In each case there was complete relief of symptoms. Early diagnosis and eradication are dependent on the recognition of the lesion by the general practitioner when he is consulted.

Glomus enlargements, or arteriovenous shunts, occur normally in skin and subcutaneous tissue. They occur most frequently in the finger tips, where they regulate temperature when the hands are exposed to cold. With increased growth of these tumors, they become excruciatingly painful. They are usually located under the nail in the visible part, or as far back as the root of the nail under the skin, where they may be more obscure. The most common source of histologic material for the study of the glomus has been the foot of the goose, where the glomus attains a large size normally and maintains the temperature of the foot. These shunts never have been found in cold blooded animals such as the reptiles.

Mason and Weil[5] have written the most comprehensive report on glomus tumors. They stressed the wide distribution of the tumors aside from the usual subungual location. They found the tumors located over the acromion, on the palmar surface of a finger, in the forearm, in the arm at the insertion of the deltoid, in the thigh, in the leg, in the knee joint, under the toenails and in the sole of the foot. The essential finding which should lead one to suspect a glomus tumor is any very painful, discreet region of trigger-like pain, where a small grayish blue or reddish purple nodule can be palpated or seen. In the differential diagnosis, subungual hematoma, fibroma, epithelioma, angioma, neuroma and melanoma have been mentioned, but in none of these is there the typical paroxysm of pain.

Treatment of the lesion consists in simple excision. The tumors are well encapsulated and easily shelled out. Occasionally the tumor may be very tiny and found with difficulty. In these cases Love[2-4] uses the "pin test," consisting of locating the tumor by means of a sharp pin; after it is found, the pin is left in place while nerve block is performed with procaine at the base of the finger. In this manner, the lesion can be completely removed, as its exact location is known.

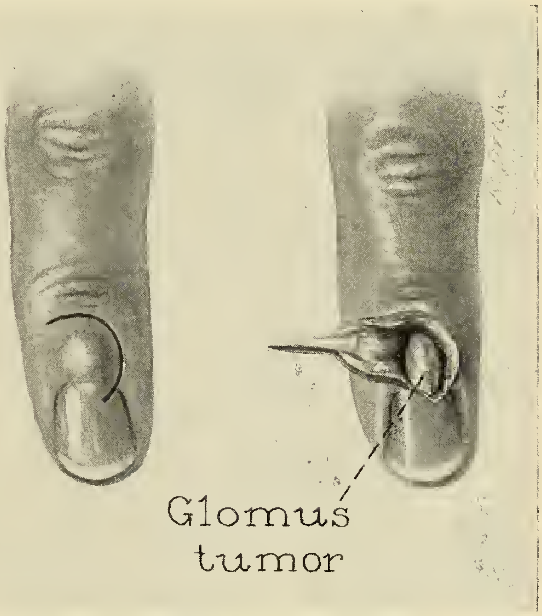

Fig. 1. Position and small size of glomangioma, also incision for removal. The majority of these tumors are subungual.

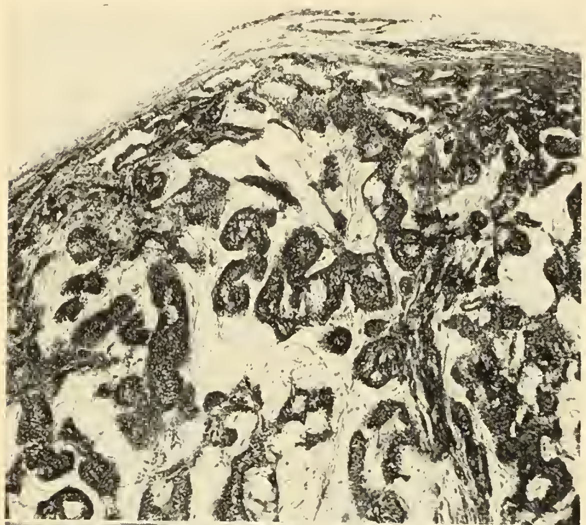
The tumors are essentially neuromyo-arterial nodules in the subcutaneous tissue as described by Dockerty.[1] The arteriovenous short circuits consist essentially of (1) an afferent arteriole, (2) an efferent venule, (3) various small connecting loops lined by endothelium, the canals described by Sucquet-Hoyer. These canals can be opened or closed quickly as a result of local nerve reflexes. The nodules are usually very small bluish ones that are exquisitely tender. Microscopically, there are anastomosing vascular spaces, some with thick walls, others with thin walls. Around these vessels there are numerous small cells, which resemble nevus cells (small with oval nuclei, small nucleoli and speckled chromatin). Some pathologists consider these cells to be endothelial in ori-

---

Dr. Meyerding is in the Section on Orthopedic Surgery, Mayo Clinic, and Dr. Varney is a Fellow in Orthopedic Surgery, Mayo Foundation, Rochester, Minnesota.

gin; others consider them to be epithelioid cells or even myoblasts. Smooth muscle and nerve fibrils may be seen intermingled with the other elements. The presence of oval, dark-staining cells in a vascular network with occasional nerve fibers and end organs should determine the diagnosis.



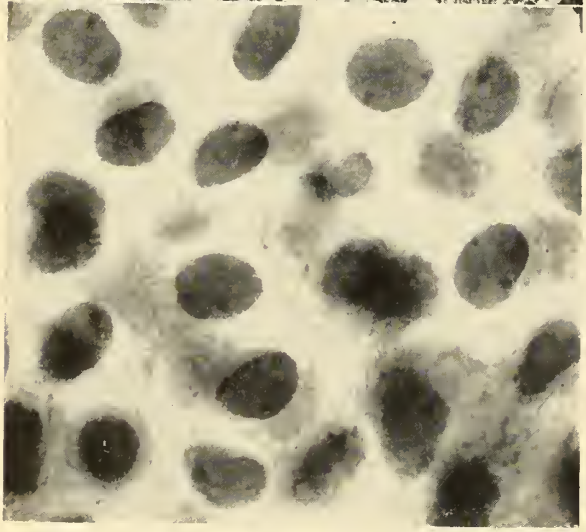


Fig. 2. *(above)* Encapsulated glomangioma showing the general architecture with small nests of nevus-like cells in a myxomatous stroma. Several dilated vascular canals are visible at the top of the photograph (× 35).

Fig. 3. *(below)* High power detail of the endothelial, nevus-like cells comprising the bulk of the tumor (× 1,300).

Report of Cases

Case 1.—A housewife, forty years of age, reported at the Mayo Clinic with a history of an excruciatingly painful region of the right fifth finger, which was located under the base of the nail bed and had been present for nine years. The pain occurred with any pressure on this region and even the weight of the bedclothes would awaken her at night. The pain was trigger-like, sharp and shooting and extended up the finger as far as the proximal phalangeal joint. She had noticed that the tumor turned reddish purple and enlarged during the painful spasm. With time, it had shown a slow increase in size and had become more painful. If she struck the finger the pain was so intense that she would turn pale and become faint. It was necessary to immerse the hand in as hot water as she could stand in order to obtain relief from her pain. The pain was more readily precipitated during cold weather than at other times. She had consulted a number of physicians during the nine years prior to admission and a diagnosis of arthritis of the terminal joint of the fifth finger had been made. She avoided shaking hands and was in constant fear of the recurrent paroxysms of pain. Physical examination revealed a small dusky red tumor under the right fifth subungual region. Almost all of it was lying under the cover of the skin at the base of the nail (Fig. 1).

The tumor was removed while the patient was under regional procaine block and tourniquet. A curved incision was used, incising part of the nail and extending up into the skin. Immediately beneath the upper part of the matrix could be seen a firm, grayish, rounded tumor, 5 mm. in diameter, which was dissected free and removed in toto. The grayish color of this tumor resulted from pressure under the nail and the tourniquet. The pathologist reported this tissue as an encapsulated subungual glomangioma (Figs. 2 and 3). The incision healed by primary intention and the patient experienced complete relief of symptoms.

Case 2.—A housewife, forty-two years of age, complained of a painful tumor located on the mesial aspect of the distal phalanx of the left index finger, which had been present for more than sixteen years and had interfered with her work. It had been operated on twice, the last time being about fourteen years prior to her admission at the Mayo Clinic. However, the tumor had not been located and the patient had not obtained relief of symptoms. Examination revealed a mass of scarlike tissue, which was tender on palpation. The roentgenograms showed this mass to be confined to the soft tissues. The roentgenograms of the lungs were negative. The blood count, urinalysis and flocculation test gave negative results. Excision of the tumor was performed while the patient was under regional procaine block and tourniquet. A small nerve and a blood vessel were seen entering the scarlike mass proximally. These were cut and tied. The surgeon suspected that the lesion was a neurofibroma but when the pathologist examined the tissue, he found that it was a glomus tumor. The tumor itself was very small, 1 mm., and was surrounded by fibrous tissue from previous operations. A number of sections had to be cut to find the hemangiomatous tissue with the typical oval, dark-staining cells of a glomus tumor. The incision healed by primary intention and the patient obtained relief from her symptoms.

CHRONIC MASTOIDITIS WITH CHOLESTEATOMA AND STENOSIS OF THE EXTERNAL AUDITORY MEATUS

Report of Two Cases

H. I. LILLIE, M.D., and JAMES B. McBEAN, M.D.
Rochester, Minnesota

IT IS well known that stenosis of the external auditory canals presents a diagnostic problem in cases in which pain or discharge is present. The following cases are presented with two purposes in mind: first, to call attention to this difficult diagnostic problem, and second, to emphasize the importance of adequate drainage in cases of chronic otitis media.

Stenosis of the external auditory canal may be congenital, in which case the patient has no symptoms referable to the ear and it is usually possible to insert a small ear speculum and obtain a reasonably satisfactory view of a normal tympanic membrane. Acute otitis externa frequently produces such swelling in the auditory canal that inspection of the tympanic membrane is impossible. In these cases the disease is of short duration, the pain is localized in the ear itself and there is pain on moving the auricle or pressing on the tragus. If a small speculum can be inserted and the discharge cleaned out, the hearing is found to be normal.

When stenosis is produced by chronic otitis media, there will be a long history of discharge from the ear. The pain is more deep-seated, the patient usually complains of deep headache in the temporal and mastoid region, and the hearing is usually much diminished. There is no pain on movement of the auricle but there may be a deep mastoid tenderness.

Report of Cases

Case 1.—A white man, aged twenty-two years, registered at the Mayo Clinic on April 16, 1946. He complained of discharge from the left ear since the age of six years. At that time he had a head injury, was not unconscious but was "dazed" for a day or two. He did not remember whether there was bleeding from the ear at that time. There had been a constant dull ache in the ear for a long time with occasional exacerbation of more severe pain. At the time of examination he was having severe steady pain in the ear and left side of the head.

Examination revealed almost complete stenosis of the left external auditory canal with purulent, foul smelling discharge present. There was profound conduction type deafness on the left. General physical examination gave negative results. On roentgenographic examination, sclerosis of the left mastoid was observed. On April 18, 1946, the left mastoid was explored through a postauricular incision. Hypertrophic osteitis had caused considerable sclerosis but there were still a large number of cells present, all of which contained pus under pressure. These cells were uncovered in the mastoid tip, behind and above the knee of the sigmoid sinus. In the region of the mastoid antrum a large abscess had uncovered the dura of the middle fossa. A tract of infected cells was explored inferior to the labyrinth leading toward the petrous apex. In the middle ear, medial to the stenosis of the external canal, was a large cholesteatoma. This was removed. The cholesteatoma had caused a large cavitation in the middle ear and adjacent tissues. Radical mastoidectomy was completed by removing the posterior bony wall of the external canal, making one cavity of the external canal, middle ear and mastoid cavity. A plastic skin flap was cut in the membranous canal and turned back into the cavity, which was lightly packed with vaselin gauze. The wound was tightly closed.

The patient's postoperative course was smooth and uneventful. Penicillin, 160,000 units daily, was administered. He was dismissed from the hospital on the eighth postoperative day and observed in the clinic for three weeks. All discomfort and pain had disappeared.

He was seen again two months later, at which time he felt well and made no complaints. The cavity had become almost completely epithelized.

Case 2.—A white, married woman, aged thirty-nine, registered at the Mayo Clinic on April 15, 1946. She gave a history of purulent discharge from the right ear since an attack of measles when she was eight years old. In the past five years she had had four exacerbations with severe pain, lasting about three weeks and relieved when the ear discharged profusely. During these episodes the pain was worse at night than during the day.

Examination revealed severe stenosis of the right external auditory canal with purulent discharge present. The stenosis prevented examination of the tympanic membrane. There was a moderately severe conduction type deafness on the right. General physical examination revealed mild asthmatic bronchitis and rheumatic mitral endocarditis. On roentgenographic examination partial sclerosis of the right mastoid was observed.

Exploration of the right mastoid process was done on April 20, 1946. There was extensive cellular development and the intercellular septa were sclerosed. The cells contained greenish brown fluid and thickened mucous membrane. Cells were removed in the tip, around

FURTHER OBSERVATIONS ON THE PROGNOSIS IN ANGINA PECTORIS DUE TO CORONARY SCLEROSIS

A Study of 405 Patients Who Survived Ten or More Years

GEORGE E. MONTGOMERY, JR., M.D., THOMAS J. DRY, M.B., and ROBERT P. GAGE, M.S.
Rochester, Minnesota

IN MAY, 1946, Parker, Dry, Willius and Gage[1] reported on the survival rate of 3,440 patients who had angina pectoris due to coronary sclerosis.

The conclusions of this study, in effect, were: (1) the highest mortality rate occurs in the first years after the onset of the disease; (2) the survival rate was definitely lower when the disease manifested itself before patients were forty years old than when they were older; (3) the survival rate of females was greater than that of males; (4) when sclerosis of the choroidal arteries was associated, the five-year survival rate was much lower than it was when this condition was absent, and (5) associated cardiac hypertrophy, hypertension (especially hypertension of groups 3 and 4 of the Keith and Wagener[2] classification), previous myocardial infarction, congestive heart failure and significant electrocardiographic abnormalities (particularly conduction defects and disturbances of rhythm) all influence prognostic trends adversely. Attention was drawn to the curious observation that the inverted $T_{1,2}$ pattern seems to be associated with a less favorable prognosis than all other types of inverted T wave patterns.

Among this group of 3,440 patients were 405 who had survived ten years or longer after the diagnosis of angina pectoris was made at the Mayo Clinic. The following report is based on a more detailed analysis of this group. A study of data about patients who have survived for a long time has the advantage of providing a viewpoint in retrospect which serves to reflect prognostic trends.

When information concerning these 405 patients was last received, 281 (69.4 per cent) of the group were still living; fifty-four (13.3 per cent) were known to have died of cardiac disease; eighteen (4.4 per cent) had died of other disease, and fifty-two (12.8 per cent) had died of unknown causes.

TABLE I. AGE OF PATIENTS AT TIME OF DIAGNOSIS OF ANGINA PECTORIS AT THE CLINIC.

Age of patients, years	Cases	Per cent
20-29	2	0.5
30-39	11	2.7
40-49	96	23.7
50-59	177	43.8
60-69	109	26.9
70-79	9	2.2
80-89	1	0.2
Total	405	100
Mean age	55.1 years	

In general, the age distribution at the time of diagnosis at the clinic of this long-surviving group (Table I) was similar to that noted by Parker and his co-workers[1] for the entire group, the average age being four years younger. However, the sex ratio shows an interesting change, for, whereas it was reported as 4.3 males to 1 female for the whole group, we found that, of the 405 patients who survived ten years, 292 were men and 113 were women, a ratio of 2.6 to 1. This change in the sex ratio reflects emphatically the well-known fact that females who have the disease survive much longer than males who have the disease.

As in the original study, we found that those patients who had cardiac enlargement, congestive heart failure and the more severe type of hypertension, and those who had choroidal sclerosis, did not fare well. They were poorly represented among these long survivors. Thus, only sixty-eight (16.8 per cent) of the 405 patients were found to have had cardiac enlargement; only ten patients (2.5 per cent) gave a history indicative of an episode of congestive failure; only seventy-nine patients (19.5 per cent) had hypertension, and none of these had hypertension group 3 or 4. In only fifteen of 237 cases in which a record of funduscopic examinations was found, was sclerosis of the choroidal arteries present at the time of the original diagnosis of angina pectoris at the clinic.

Dr. George E. Montgomery, Jr., is a Fellow in Medicine, Mayo Foundation, Rochester, Minnesota; Thomas J. Dry is a member of the Division of Medicine, Mayo Clinic, and Robert P. Gage is with the Division of Biometry and Medical Statistics, Mayo Clinic, Rochester, Minnesota.

Influence of Acute Myocardial Infarction

At the time of the original diagnosis of angina pectoris at the clinic, seventy-one patients (17.5 per cent) had had previous coronary occlusion. Only 3.7 per cent of the patients in the group are known to have had coronary occlusion subsequently. While others may have had unrecognized or unreported episodes of myocardial infarction, the number is impressively small among those who survived for ten years or longer after the diagnosis was made at the clinic. Isolated instances of multiple infarction among the long survivors provide the exception that proves the rule.

Electrocardiographic Findings

A detailed study of the electrocardiograms was made in these 405 cases in an effort to determine what, if any, are the significant changes that may occur which would aid the physician in giving a correct prognosis to the patient suffering from angina pectoris.

In 236 cases (58.3 per cent) in this group, the initial electrocardiagram was considered to be normal. The electrocardiographic abnormalities among the remainder consisted mainly of (1) inversions of the T wave, which can be considered to be either relics of acute myocardial infarction or the result of hypertension; (2) auriculoventricular and intraventricular conduction disturbances of various types, and (3) disturbances of rhythm (Table II). The relative infrequency with which the initial electrocardiogram revealed conduction disturbances, and the infrequency with which it revealed ectopic rhythm in this long-surviving group, reflect a significant prognostic trend and need no further comment. As far as abnormalities of the T wave are concerned, the point worthy of re-emphasis is the infrequency (seven cases) with which the inverted $T_{1,2}$ pattern occurs in this group in comparison with all other abnormalities of the T wave. There were thirty cases in which the electrocardiographic findings became normal after having been found to be abnormal initially. In only one was the original abnormality an inversion of the $T_{1,2}$ waves. The remainder of the abnormalities were divided about equally among T_1 inversion, $T_{2,3}$ inversion and $T_{1,2,3}$ inversion. What makes this fundamental prognostic difference between this $T_{1,2}$ pattern on the one hand and the T_1 pattern (and for that matter other combinations of inversions of the T waves) on the other, is difficult to explain.

TABLE II. ELECTROCARDIOGRAPHIC FINDINGS AT TIME OF DIAGNOSIS IN PATIENTS SURVIVING TEN YEARS OR MORE WITH ANGINA PECTORIS.

Electrocardiographic findings	Cases*	Per Cent
Normal	236	58.3
Inverted T^{1}	44	10.9
Inverted $T^{1,2}$	7	1.7
Inverted $T^{2,3}$	43	10.6
Inverted $T^{1,2,3}$	14	3.4
Left bundle-branch block (concordant)	9	2.2
Left bundle-branch block (discordant)	1	0.2
Right bundle-branch block	0	—
Wide S wave	2	0.5
Complete heart block	0	—
Delayed auriculoventricular conduction	3	0.7
Auricular fibrillation	3	0.7

*No totals are given because several of the noncontributory electrocardiographic classifications are omitted.

In 154 cases, subsequent electrocardiograms were available for further study and for comparison with those obtained at the clinic at the time of the diagnosis of angina pectoris.

It is noteworthy that in sixty-seven cases in which the original electrocardiogram was normal, no significant changes occurred in the subsequent electrocardiograms. These sixty-seven cases comprised 70 per cent of those in the group of 154 cases in which the original electrocardiogram was normal. Moreover, in half of the cases in which the electrocardiographic findings were originally abnormal, they were found to have returned to normal at a subsequent examination. This illustrates the tendency for the electrocardiographic findings to remain normal or to return to normal among the long-surviving subjects with angina pectoris due to coronary sclerosis.

The prognostic trend in so far as the electrocardiographic criteria are concerned is reflected further by comparing the five-year survival rate of all patients who had angina pectoris due to coronary sclerosis with the survival rate among our group who lived ten years or longer (Table III).

Comment

The normal heart possesses collateral channels which may, for the most part, remain functionless until occlusive changes in the main arteries or their branches stimulate them to supplement

*Inquiry as of January 1, 1942. The five-year group includes only those cases in which the diagnosis of angina pectoris was made five or more years prior to the time of inquiry, that is, 1936 or earlier; the ten-year group includes only those cases diagnosed in 1931 or earlier.

†No totals are given because several of the noncontributory electrocardiographic classifications are omitted.

the arterial supply to the myocardium. Herein might lie congenital or hereditary factors which decide the fate of the individual patient who has coronary arteriosclerosis and its complications. Because coronary sclerosis is inevitable with aging and at times is accelerated by coexistent disease, such as hypertension, diabetes, obesity or myxedema, the future course can well be pictured to depend on which process—the occlusive or the supplemental—exhibits the greater potentiality toward progression.

Given an instance in which the arteriosclerotic process in itself is diffuse and rapidly progressive or in which the anatomic arrangement of the main coronary arteries is such that the left ventricle receives its blood supply almost entirely from one or the other of the coronary arteries (thus vitiating the establishment of adequate supplemental circulation should this important channel become sclerotic) or in which the clinical course is punctuated by repeated episodes of myocardial infarction, the outlook must of necessity be unfavorable. However, given an instance in which the occlusive process is slow or limits itself to a minor branch of a coronary artery, in which the groundwork for collateral circulation is unusually adequate because of a fortuitously favorable anatomic arrangement of the coronary vessels or in which factors capable of aggravating arteriosclerosis are absent, the outlook is more favorable and acute myocardial infarction constitutes a much less hazardous event. It is possible that a minor occlusive episode in certain instances such as these, may even stimulate the establishment of collateral circulation. Therefore, the fact that the mortality rate is high in the earlier years after the inception of this disease is understood readily. In those cases in which the coronary circulation is prepared against the effects of both gradual and sudden interference with arterial supply the patients can be expected to survive this stormy period.

Finally, we can speculate, with some reservations, on the degree to which treatment influences prognosis. Given a large number of patients suffering from the same disease who can be assumed to receive essentially the same treatment what, other than natural endowments inherent in coronary circulation, could account for the wide variation in the subsequent course? One answer might well be the difference in ability of patients to make the necessary physical and psychologic adjustments which the disease imposes. The limiting effect of anginal pain ordinarily precludes overindulgence in physical activity. Unfortunately, this is not always true of overindulgence at the table. Still less can we expect successful psychologic adjustments in patients already in middle age or older, whose habits have become fixed, who often have reached the most responsible part of their life and who inherently fear the possibility of a cardiac disorder. Fear, as a potent vasoconstrictor, can only influence the successful establishment of collateral circulation adversely and perhaps to an extent more lastingly than some other environmental influences, not excluding excesses in some habits.

Summary and Conclusions

In this report, data concerning 405 cases in which the patients survived ten years or longer after the diagnosis of coronary sclerosis and angina pectoris were analyzed.

The ratio of men to women in this group was 2.6 to 1.

This study further revealed that cardiac enlargement, coronary occlusion and congestive heart failure, when associated with angina pectoris, definitely increase the mortality rate. The infrequent occurrence of choroidal sclerosis in this group indicates that it is an unfavorable prognostic finding.

Not a single patient with hypertension, group 3 or 4, was represented in this long-surviving group.

The number of cases in which electrocardiographic findings were normal in this group was high. In addition, when initial and subsequent electrocardiograms were compared a tendency of the electrocardiographic findings to revert toward normal was noted in cases in which they were initially abnormal. The negative $T_{1,2}$ pattern apparently indicates unusually severe damage to the heart, because for patients who had this abnormality in their initial electrocardiogram, the mortality rate was extremely high as compared to other patterns which are considered to be relics of previous myocardial infarction.

In the final analysis, the most potent factor in determining prognostic trends probably centers around the success or failure of establishment of adequate intercoronary anastomoses.

CHRONIC MASTOIDITIS

(Continued from Page 161)

and posterior to the sigmoid sinus, and in the root of the zygoma. The dura of the middle fossa had been exposed by the disease process in two places. The middle ear and external canal medial to the stenosis were packed with cholesteatoma, which was removed. Radical mastoidectomy was done and a plastic flap was turned back from the external membranous canal. The cavity was lightly packed and the incision was closed. The postoperative course was uneventful and the patient was given penicillin, 160,000 units daily, for four days. She had no further pain. She returned for observation two months later, at which time she felt well. The ear canal was open and the mastoid cavity was almost dry.

Comment

The first patient had been recently discharged from the army. While overseas, he had had a flare-up in his ear and had been treated for otitis externa. The character of his pain and the history of discharge for many years should have enabled the attending physician to make the diagnosis. In both cases, the severe stenosis of the canals had prevented adequate drainage from what otherwise might have been benign otitis media. In both cases the infection had spread throughout extensively pneumatized mastoid processes and had uncovered the dura, forming an epidural abscess in one case. Irritation of the exposed dura is the cause of the deep-seated pain.

In both cases cholesteatoma had formed medial to the stenosis of the ear canal. This is due to the piling up of desquamated epithelium.

Summary

Two cases of extensive chronic mastoiditis with stenosis of the external auditory canal are presented in which the extensive disease process and cholesteatoma are aggravated by lack of adequate drainage. In order to prevent extension to intracranial structures or to the sigmoid sinus, surgical intervention is urgent in cases of chronic otitis media when there is obstruction of drainage due to stenosis of the external auditory canal. No other type of treatment is adequate.

POLYNEURITIS

Differentiation of Infectious Polyneuritis (Guillain-Barré Syndrome) and the Neuritis of Porphyria

MAJOR CHARLES L. YEAGER, Medical Corps, AUS
Waco, Texas

IN the study of multiple neuritis, two syndromes merit careful clinical differentiation: the so-called infectious polyneuritis or Guillain-Barré syndrome, and the polyneuritis of acute porphyria. Each has been presented at length in the literature, but a close diagnostic differentiation has not been made between them. During an acute episode of porphyria, the neuritis may not differ from polyneuritis of any cause; but similarities are even more striking between the so-called acute infectious polyneuritis and porphyria because of the obscurity of etiology in both cases, the traceable toxic factors in many cases of porphyria, the equally rapid onset of symptoms in both cases, and the similarity in length and course of the two diseases. However, the difference in prognosis is so striking that the two conditions should be differentiated early. In infectious polyneuritis, one may feel reasonably assured of recovery, whereas, in porphyria, an ultimate fatal outcome is anticipated.

Several splendid reviews of the literature have been written describing infectious polyneuritis[5,6,16,18] and porphyria,[8-12] to which the reader may refer for more complete discussion.

Infectious Polyneuritis (Guillain-Barré Syndrome)

In 1892, Osler[15] described a form of acute febrile polyneuritis with Landry's ascending type of paralysis. In 1916, Guillain-Barré and Strohl[7] likewise demonstrated cases of supposed infectious polyneuritis in which the spinal fluid contained high quantities of protein and low cellular content, known as albuminocytologic dissociation, which in combination with multiple neuritis has come to be known as the Guillain-Barré syndrome. Other terms describing the condition are encountered with confusing frequency.[16]

The cause of infectious polyneuritis has not been adequately demonstrated. Both Osler[15] and Guillain[6] believed that the condition had an infectious etiology, but Gilpin and his associates[3] were of the opinion that a virus is the causative agent. The disease is no respector of persons, and both sexes are affected equally. Although no age is exempt, the majority of cases occur in individuals between the ages of twenty and forty. There is no apparent diathesis for the disease, and the strong and otherwise healthy person may be struck down. Cases occur both epidemically and sporadically, but there is some seasonal variation, the greater incidence paralleling upper respiratory infections in changeable fall and spring weather. Familial and hereditary tendencies are not demonstrable. As a rule, psychogenic symptoms and personality disturbances are not elicited.

The Guillain-Barré syndrome is a multiple neuritis, involving in various degrees the peripheral spinal nerves and nerve roots, as well as the cranial nerves. Of the cranial nerves, the seventh nerves are the most commonly affected, resulting in unilateral or bilateral facial palsy. The motor nerves are more severely involved than the sensory.

Frequently, at the outset, the otherwise healthy individual is stricken with an acute upper respiratory infection which is accompanied by mild to moderate fever, malaise and gastrointestinal disturbances. The acute episode subsides and complete recovery is apparent.

Within a few days to a few weeks, the first signs of neuritis become apparent. Although ultimately impairment of motor nerve function is more severe than impairment of sensory function, sensory symptoms may appear long before weakness is noted. At the outset, there are paresthesias of the hands and feet, deep aching and tenderness of the large muscle groups of the extremities and body, and scattered areas of dyseshesia and paresthesia over the body and face. In some cases, there is no demonstrable objective sensory deficit throughout the course of the disease; in others, glove and stocking type of sensory loss develops in all modialities.

Days or weeks after the appearance of sensory changes, progressive flaccid paralysis sets in, beginning in the distal portion of the lower extremities or of the lower and upper extremities simultaneously, and spreading proximally in the pattern of Landry's paralysis. Weakness is usually uniformly bilateral, but impairment may show unilateral predominance. While the onset of weakness is in the fine distal muscles, the large proximal muscles of the shoulder and pelvic girdles, arms and thighs, are most severely affected. When the paralysis reaches its maximum, any remaining movement is confined to the small muscles of the hands and feet. As paralysis ascends, the large muscles of the trunk fail, and respiration is embarrassed by paralysis of the intercostal nerves so that the burden of respiration is placed upon the diaphragm. If the diaphragm fails, death may ensue. It has been noted that if paralysis is sufficiently complete to warrant the use of a respirator, death is imminent.

Development of the disease is dramatic and very incapacitating, yet the prognosis is exceedingly favorable. The mortality rate varies from 16 to 25 per cent, but good nursing care through the critical period in which the patient is helpless frequently averts death. A good prognostic maxim is that if one is able, by any means, to keep the patient alive during the critical period of maximum paralysis, complete recovery is reasonably assured.

All the cranial nerves may be involved. The seventh is the most susceptible, resulting in bilateral peripheral palsy with facial diplegia.[1] The extrinsic muscles of the eye may become noticeably affected, resulting in partial or complete fixation of the eyeball. Paralysis of the intrinsic muscles of the eye, as well, has been observed. Sensation of the face may be changed, both subjectively and objectively. Hearing is seldom affected. Involvement of the ninth, tenth, eleventh and twelfth nerves present numerous and various patterns of disturbance, resulting in deglutition, taste loss, taste distortion, increased salivary secretion and disarticulate speech.

All deep reflexes are lost, but the superficial reflexes are usually preserved. Signs of pyramidal tract involvement are lacking, muscles are flabby, and tone is destroyed. The picture is that of a lower motor neuron paralysis.

Accurate co-ordination studies are seldom obtained because of the marked motor disability. Response to galvanic and foradic stimulation is reduced or lost.

Although albuminocytologic disassociation in the cerebrospinal fluid is a common finding, the phenomenon is by no means constant. The fluid may be under increased pressure. Some of the cases described by Gilpin et al[3] showed choking of the optic disc, indicating significant increase in intracranial pressure. Systematically, there may be evidence of liver and heart damage.

Pathologic changes are not specific. The peripheral nervous system is primarily involved, resulting in demyelinization and Wallerian degeneration. Severe neuron changes in the central nervous system have been demonstrated. There may be edema of the brain and spinal cord with scattered petechial hemorrhages.

Treatment is supportative, and success hinges on skilled nursing care. Although the administration of vitamins is routine, little can actually be said in its behalf. Recovery follows with or without vitamin intake. The administration of beer and salt, although strictly empirical, seems to be a pleasant source of vitamins and minerals. Physiotherapy helps to maintain muscle tone and prepares the individual for more rapid recovery when nerve regeneration develops.

Polyneuritis with Porphyria

Porphyria is a heredofamilial constitutional disorder of pigment metabolism with protean manifestations, resulting in excretion of large quantities of uroporphyrin and coproporphyrin in the urine.

A red complex pigment termed hematoporphyrin was originally synthetized by the action of strong sulphuric acid on hemoglobin.[8,10,12,13,21] It has been demonstrated that hematoporphyrin occurs normally in small amounts in the urine.[8,11,14] In 1911, Gunther[8] described a condition in which pigments were excreted in the urine in such large quantities that the urine became a dark burgundy wine color. He attributed the condition to an anomaly of pigment metabolism and called the disease hematoporphyria. In 1924, Fischer[2] demonstrated that individuals with hematoporphyria excreted gross quantities of uroporphyrin and coproporphyrin in the urine but not hematoporphyrin, which apparently does not appear in nature but is only a laboratory product. Therefore, porphyria is considered the correct terminology for the disease in question.

The porphyrias are classified into chronic porphyria, congenital porphyria and acute porphyria. Acute porphyria takes on two forms with identical clinical manifestations, but presumably the acute toxic form is distinguished from the idiopathic form only by evidence of some toxic substance acting as the precipitating agent.[11,13,20]

Chronic porphyria is a neuropathic disease which is manifested by signs of chronic nervous system irritation. There are recurrent episodes of irritability, restlessness, insomnia and multiple vague gastro-intestinal complaints. Porphyrins may or may not be excreted in the urine. The condition is referred to as "porphyrismis." Considerable doubt exists as to whether there is such a disease entity.

Congenital and acute porphyria differ not only symptomatically but also, according to the beliefs of Gunther,[9,19] in their basic constitutional diatheses. The underlying abnormal basis of the congenital form was referred to as "porphyrosis" and that of the acute form as "porphyrism." Even though, in porphyrosis, manifestations are systemic, there is a definite but hidden neuropathic constitutional factor. In porphyrism, on the other hand, the nervous system is directly involved, giving rise to general nervousness, anxiety reaction, insomnia, irritability, depression and organic psychotic reactions (delirium).

Congenital porphyria, a Mendelian recessive disease, dominant in males, is characterized by its development in early infancy, the appearance of large quantities of porphyrins and other pigments in the urine, and photosensitive skin with purplish brown pigmentation of the skin and teeth. The pigmentation is the result of deposits of uroporphyrin I in the sublayers of the skin and teeth. Uroporphyrin I is excreted in large quantities in the urine. The predominant skin lesions are the disfiguring hydro-aestivale or vacciniforme. Photosensitivity, in the presence of exposure to intense or prolonged light, leads to restlessness, generalized pruritis, accelerated pulse and respiration, weakness, coma and possibly death. Skin necrosis may develop secondary to vascular constriction. Recurrent episodes lead to chronic hardening of the skin, resembling scleraderma.

Acute porphyria is inherited as a Mendelian dominant, appears later in life, usually during the third or fourth decade, is more frequent in females than in males in a ratio of 3:1. Photosensitivity and discoloration of the teeth are rare; largely, uroporphyrin III is excreted in the urine.

Acute porphyria has been subclassified as acute idiopathic porphyria and acute toxic porphyria. The diseases are indistinguishable. The latter differs etiologically in that there is an apparent idiosyncrasy to certain toxic agents, among which are acetanilid, nitrobenzol, barbiturates and sulfonamides. Latent forms[13,17,20,21] of porphyria have been described in which abnormal quantities of porphyrins are excreted in the urine in the absence of clinical symptoms. Conversely,[17,21] characteristic symptoms may appear in the absence of excretion of porphyrins. The porphyrin pigments may appear only during the peak of an attack, disappearing from the urine as symptoms subside, or the urine may remain free of porphyrins even during the height of an attack, but the symptoms and signs warrant the diagnosis. The condition in which porphyrins are not present was referred to by Waldenstrom[21] as "porphyria without porphyrins."

Acute porphyria is really a chronic familial disease characterized by exacerbations and remissions. Family and early personal history indicate numerous ill-defined nervous manifestations which may be considered in the category of psychoneurosis.

The disease is manifested clinically by recurrent colic-like abdominal pain, involving the lower quadrants and centering about the umbilicus with radiation to the flanks, thighs or chest. An acute episode may be preceded for months by unexplained weakness, nervousness, sleeplessness, and vague flitting pains in the abdomen and extremities.

The protracted mild illness is followed by sudden onset of severe abdominal cramps, nausea, vomiting, severe constipation, accompanied by fever and leukosytosis. The abdomen is soft, but excruciatingly tender. X-ray of the abdomen reveals dilatation of the duodenum, ileum or large bowel. There may be signs of paralytic ileus. The general physical examination is usually normal. During the attack, the urine is the color of burgundy wine and contains porphyrins. Watson and Schwartz[22] devised a simple test for porphobilinogen, a colorless chromogen substance, which when found in the urine is pathognomonic of acute porphyria. Approximately 80 per cent of individuals with porphyria, in contrast to the 20 per cent with the Guillain-Barré form of polyneuritis, ultimately terminate fatally.

Common among the neurologic signs is paresis and paralysis. Both efferent somatic and efferent sympathetic motor nervous systems are affected by the disease. Among the more frequent forms of paralysis is Landry's ascending type, which may result in death if the respiratory muscles are paralyzed. Waldenstrom[21] and Roth[17] have pointed out that irregular forms of paralysis involving scattered groups of muscles are equally common. Although subjective sensory symptoms in the form of paresthesias occur, in consideration of the severity of motor involvement the absence of sensory defect is notable. Paralysis is of the flaccid type, involving all of the extremities, and may involve all cranial nerves, leading to signs of acute bulbar palsy with dysphagia, dysphonia and asphyxia. All deep reflexes become obliterated, but the superficial abdominal and cremasteric reflexes may be preserved. In a number of cases described by Gunther,[8-10] anesthesia was widespread.

Involvement of the sympathetic nervous system as a result of changes in the abdominal autonomic ganglia is held responsible for the signs of constipation, colic and paralytic ileus.

One of the properties of porphyrins is the ability to produce spasm of smooth muscle,[14] resulting in hypertension, oliguria, neuritis (secondary to spasm of the nutrient vessels of nerves) and amaurosis (secondary to retinal angiospasm).

Psychiatric manifestations in porphyria vary widely in type and degree and may lead to admission to a psychiatric hospital. The organic reaction type is secondary either to organic cerebral damage, as a result of degeneration of the parenchyma, or perhaps to metabolic disturbances. Gross evidence of organic damage to the brain may be lacking, and in such cases, the condition may be confused with the minor psychogenic reactions such as anxiety and hysteria, the impression being based on the vague abdominal cramps, bizarre patterns of motor weakness and transient attacks of amaurosis. These, in addition to a long history of functional nervous manifestations in the patient and members of his family, and the paucity of organic signs by exclusion lead to such misinterpretations.

Pathologic studies in acute porphyria show scattered pigment (both iron-free and iron-containing) throughout various organs. Large quantities of pigment are deposited in the liver. Vascular thromboses leading to impairment of function of various organs of the body have been known to occur. The preponderance of pathologic changes found at autopsy, however, are in the nervous system. There are parenchymatous degenerative changes in the mixed peripheral nerves, with involvement primarily of motor fibers, scattered demyelinization, and degenerative changes in the cells of the sympathetic ganglia, horn cells of the spinal cord, and Purkinje cells of the cerebellum. Although the peripheral nervous system and lower segments of the cord are involved more completely than the higher segments of the cord, bulbar signs, from time to time, are predominant.

In the congenital forms, pigment is deposited throughout the body, and pathologic changes within the nervous system are minimal.

Case Reports

Case 1. An enlisted WAC, aged twenty-five, was admitted to Lawson General Hospital, June 11, 1944.

Several days following a cold, the patient noted weakness and pain in the legs and numbness of the hands and feet on May 25, 1944. At that time, examination in the infirmary was not remarkable except for a slight dragging of both feet in walking. Because of increased disability in walking, it was felt advisable on May 27 to have her admitted to the station hospital. By May 30, walking was impossible, but paralysis continued to increase so that by June 11 it was complete in both lower extremities and trunk. Slight movement, however, persisted in the upper extremities. She could roll her head from side to side, but could not raise it. The muscles of her face and extrinsic muscles of her eyes were but slightly affected. All deep reflexes were absent. Flexion of the knee, hip and back was painful. Paresthesias of the extremities persisted. Fever and other physical signs of acute infection were absent.

Admission blood count, as well as subsequent blood counts, was within normal limits. Urinalysis was repeatedly normal. Examination of the spinal fluid on June 11 showed a very slight xanthochromic fluid which contained a 169 RBC and an occasional white cell. Smear and culture were normal. Sugar was 83 mg. per cent. X-ray of the chest on June 21 showed slight atelectasis in the anterior-posterior view, but this could not be demonstrated in the lateral view. Porphyrins were not found in the urine.

A diagnosis of Guillain-Barré syndrome was made. The patient remained afebrile. She was treated symptomatically with foot board to the extremities, frequent changes of position and high vitamin diet. On two occasions, she developed dyspnea which was considered due to atelectasis, and which disappeared with frequent changes in position. By June 25, a month after onset of the disease, improvement in strength was noted. Physiotherapy, which was begun shortly after admission, was continued and by the first of August the patient was able to mobilize enough strength to move about the bed without aid, but not until September was she able to walk without assistance. Improvement in strength continued until October 4, at which time a thirty-day furlough for continued convalescence was granted. She returned from the furlough in good condition November 3, and after a further brief period of convalescence, she was pronounced fit for full duty and was discharged from the hospital.

Case 2. A lieutenant colonel of the Air Corps, aged twenty-nine, a white, married man, who had ten and one half years of continuous service, was admitted to Lawson General Hospital on November 29, 1945.

The chief complaint on admission was generalized muscular weakness, numbness of the extremities, face and ears, disturbances of taste, and double vision.

History revealed no evidence of familial or hereditary diseases, and his personal history was entirely negative with respect to his present illness. He had no unusual childhood diseases referable to the nervous system. He was a well-educated man who has apparently been adjusted physically emotionally and socially.

Military service records revealed that he was in the tropics in Africa and the China-Burma-India Theater from August, 1942, to February, 1944.

The onset of the present illness is dated to October 1, 1945, when the patient was admitted to a station hospital in Illinois because of chills and fever. On admission, he was found to have a temperature of 103.8°. No cause for the fever was demonstrated, and evidence of malaria was lacking. The episode was considered an innocuous upper respiratory infection and on October 7, 1945, he was pronounced cured and returned to duty. Upon leaving the hospital he drove to Atlanta, Georgia, and remained well until October 14, at which time he took a fishing trip with his wife and brother. They all drank white mountain corn liquor. The others noted no ill effects but on the night of October 14, the patient after going to bed feeling well, was awakened during the night with intense nausea which soon gave way to protracted vomiting, retching and hiccups. After about three hours he was admitted to a station hospital near Atlanta, Georgia, and was found to be in partial shock. Intravenous fluids were administered with resulting improvement. At that time, he complained of difficulty in swallowing, but no positive neurologic signs were noted. The patient remained in the hospital for four days and because of improvement, he was discharged to his quarters.

On October 19, he was cognizant of all food tasting like chocolate. During the latter part of the day he was overcome by a second attack of nausea, vomiting and hiccups. He felt tingling sensation on the medial aspect of the left arm. On October 22, he experienced difficulty in focusing his eyes and became aware of double vision on looking to the right and left. By then, the paresthesias had spread to involve all extremities and his gait was staggering in character. By October 26 weakness and ataxia had progressed to an alarming degree and it was felt advisable to return him to the hospital. Upon admission, the strength of the large muscles of all four extremities was found to be noticeably reduced, and the extrinsic muscles of the eyes did not function co-ordinately, although, as yet no objective sensory deficit was demonstrable. There was a profound tenderness to deep pressure anywhere on the body. All deep reflexes were reduced but the superficial reflexes remained active. A positive Lasegue sign was found bilaterally.

Laboratory studies on readmission were essentially normal. Glucose tolerance varied from 108 to 133 milligrams per cent, sugar being found in the urine. On October 29, a spinal fluid examination showed a clear fluid with 3 lymphocytes, negative globulin, negative Wassermann, a gold curve of 0011000000, and a total protein of 60 mg. per cent.

Because of rapidly developing paralysis, the patient was transferred to Lawson General Hospital on October 29, 1945. Upon admission, examination revealed severe impairment of the cranial nerves, loss of taste, paralysis of the extrinsic muscles of the eyes with immobilization of the eyeballs, complete bilateral ptosis, and nearly complete paralysis of the facial muscles. Generalized weakness was also progressing. He described paresthesis from the toes to the face. Deep muscle tenderness and pain upon movement were increasing. The deep and superficial reflexes by then were absent. Complete glove and stocking anesthesia extending to the mid-thigh and mid-arm regions had appeared. Within twenty-four hours, the condition had progressed to such extent that only the toes of the right foot and the fingers of the right hand could be wiggled slightly. Trouble in swallowing was encountered and respiration was difficult. Because of the graveness of the patient's condition all precautions were taken. He remained in this condition until the last week in December, at which time some improvement in strength was noted. From that point on, improvement was progressive and in four months, 80 per cent of the lost strength was recoverd, and the only sensory disturbance was a mild hyperesthesia of the soles of the feet. This was considered a Guillain-Barré syndrome, and laboratory studies supported the diagnosis.

Urine porphyrins were negative. Throat cultures were negative. The spinal fluid on October 29 revealed a total protein of 60 mg. per cent, and on November 6 the total protein was 256 mg. per cent. On February 7, 1946, the total blood protein was 5.3; serum albumin, 3.7; serum globulin, 1.6; nonprotein nitrogen, 34; and urea nitrogen, 17. Cerebral spinal fluid examination on February 22, 1946, showed 160 mg. of total protein and a zone curve of 2211000000.

Case 3. A twenty-seven-year-old white WAC private of English descent, was admitted to Lawson General Hospital on April 5, 1945, complaining of paralysis of all four extremities and weakness of phonation and deglutition. At the age of five she had a tonsillectomy; at seventeen, an appendectomy; at twenty-five, because of irregular menses, a dilation and curretage was done, following which the menstrual cycle was normal. Her mother died at twenty-eight years of age of paralysis, the exact nature of which is unknown. The patient was ten years old at the time. She had a sister one year younger who had been observed in state institutions on a number of occasions because of emotional instability. There were two younger brothers, apparently healthy. The patient occasionally had tantrums which were described by her father as reminiscent of similar attacks evidenced by her mother before her death. The patient completed grammar school but interrupted high school to obtain employment as a drill press operator. After working a while with a good record, she quit to enter the army.

She enlisted in August, 1944. On January 15, 1945, she developed recurrent cramping abdominal pain associated with the passage of about five loose normal-colored stools a day. She continued to perform her clerical duties and on February 6 went home on furlough. The abdominal colic continued and at times was severe enough to cause her to double up. She vomited occasionally but sought no medical aid until her return to the army air base to which she was assigned. On February 24, 1945, she reported to the dispensary and was immediately hospitalized. Physical examination, including rectal, pelvic and neurological studies were normal, except for generalized abdominal tenderness, most pronounced in both lower quadrants. She appeared anxious and emotionally unstable. She vomited occasionally but had no diarrhea nor fever.

Laboratory studies were normal except for the urine which appeared smoky, was positive for acetone, but otherwise was negative. X-rays of the chest and gastrointestinal tract were normal, except for some pylorospasm, which was not present on subsequent examinations.

She was given intravenous fluids, barbiturates and antispasmodic drugs, in order to relieve symptoms which were at first thought to be psychiatric in origin.

On March 10, the fourteenth hospital day, she stated that she was unable to control her arms and legs, which had become weak. Movement was choreiform in nature, and the extremities trembled when motion was attempted. The loss of strength was of a bizarre nature in that she could not rise from a chair, but if assisted to a standing position, she could walk the length of the ward. The diagnosis of hysteria was seriously entertained. On March 14, she developed bilateral flank pain, blood pressure of 160/120, and the urine revealed 2 plus albuminuria, 3 to 4 white blood cells per high-powered field, and a specific gravity of 1.023. Repeated tests resulted in similar findings. The blood nonprotein nitrogen and urea were normal. A spinal puncture was performed on March 29 with normal findings throughout. During the next few days her symptoms improved. She vomited less and complained of less abdominal pain. The blood pressure fell to 132/100, but there were no changes in the urine findings. Neurological examination showed loss of all deep reflexes except the knee jerks which could be elicited if re-enforced. Her temperature occasionally rose to 100° F. in the afternoon. Considerable wasting of the extremities and apparent weight loss were noted, although the weight was not recorded.

On April 4, she was seen to pass dark colored urine which contained neither blood nor bile. Ehrlich's test for porphorobilinogen was positive. The diagnosis of acute porphyria was made, and the patient was transferred to Lawson General Hospital.

Previous clinical and laboratory findings were confirmed. The systolic blood pressure remained at 130 to 140 mm. and diastolic at 108 to 110. She lost the ability to phonate and could not talk above a whisper. Neurological examination revealed widespread flaccid paralysis of the lower motor neuron type. The muscles of the palate moved normally. The vocal cords were completely paralyzed. An electrocardiogram was normal. Examination of the urine was positive for porphorobilinogen. Coproporphyrin was observed spectroscopically in the urine on mutiple occasions. Uroporphyrin was not found. The color of the urine varied from normal to dark wine color. Total plasma protein, albumin-globulin ratio, and the blood count were normal.

She had recurrent bouts of bilateral flank pain, anorexia, and abdominal cramps, which were usually accompanied by the excretion of dark urine. Her cough was weak. She suffered several disturbing episodes of cough and dyspnea, associated with the aspiration of mucus, which were relieved only by a motor-driven suction apparatus. She required constant vigil by special nurses because she could not call out, nor could she control her arms enough to ring a bedside bell. During the early part of her hospitalization she took food and fluid poorly because of dysphagia. Her diet was augmented by intravenos fluids and parenteral vitamin concentrates. She was fitted with braces for the extremities and a special wheel chair was devised. Amenorrhea has been present since January. During June and July, muscle strength gradually, although incompletely, returned. The muscles of the trunk, shoulders, and pelvic girdle became stronger, but there was little improvement in the small muscles of the hands. The voice returned to a hoarse whisper; appetite, vigor, and spirits became much better. The patient was transferred to a veterans' facility near her home.

A diagnosis of acute porphyria was made and substantiated.

Case 4. A private in the Army Air Forces ground crew, aged eighteen, white, with three months of service, was admitted to Lawson General Hospital, December 19, 1945. His chief complaints were "spells," weakness, and "passing out." The patient's history revealed that he had had pain in his back and flanks since early childhood. A doctor had stated that he had "kidney trouble" of some type. He suffered pneumonia at the age of eleven years and had had enuresis since early childhood. The patient, however, stated that he never recalled passing any dark colored urine. However, he was not a good witness and his statements were vague. From the age of twelve, he suffered recurrent abdominal cramps of sufficient intensity to immobilize him in a flexed position. At the age of fifteen, he began to have vague fainting spells beginning with hot and cold sensations followed by dizziness and unconsciousness. They had not been accompanied by convulsions, biting of the tongue, nor loss of control of the bladder. These attacks had occurred from two or three times weekly to every three or four months. The patient quit school in the ninth grade to work as a constructor and mechanic. He did this to help support his family, but he also stated that school was difficult for him and he did not enjoy it. For many years he had been shaky, shy and introverted. He did not enjoy mixing with people and was afraid of the opposite sex. The patient stated that throughout his life he had had peculiar experiences, had thought he heard footsteps behind him but, upon looking around, no one was there. Also, on occasions he had heard his name called when no one was near. The family history was contributory, in that the father had suffered from stomach trouble for many years, had been wounded in the last war and had been hospitalized frequently. The mother suffered from asthma and had had numerous "nervous breakdowns." But as far as could be determined, there was no family history of epilepsy or mental disease. Two brothers and one sister were in good health.

The military history was short. He stated that he came into the army in September, 1945, but he did not recall the date. He began basic training but said he "couldn't take it" because of headaches and swollen throat. He had always had physical complaint, but the strenuous activity of basic training accentuated his symptoms. Before and after coming into the army, he suffered from episodes of crying, and since being in the army he had had three occasions when he would break down crying, which led to a fainting spell.

The present illness began while en route from Camp Chaffee, Arkansas, to Keesler Field, Mississippi, when he developed headache, malaise, chills, fever and sore throat. He was admitted to the station hospital, where he was treated for severe pharngitis with sulfa drugs and penicillin. Improvement was rapid and he was discharged in several days from the hospital. Repeated throat cultures were negative. He was readmitted on November 18, 1945, because of persistence of the same symptoms and an additional complaint of unsteadiness on his feet. On this admission, he was found to be ataxic and to walk with a wide gait. There was moderate in-co-ordination of the upper extremities. Further neurologic examination revealed Rhombergism, astereognosis, and abscence of the deep reflexes. The patient complained of a burning sensation in the feet which made walking uncomfortable. Deep sensibility, especially vibration, was impaired but superficial sensation was spared. All findings were more pronounced on the left. There was hesitation and blocking of speech.

The general physical examination was normal. An electrocardiogram showed evidence of left axis deviation. Laboratory studies at Keesler Field revealed normal blood and urine, and the spinal fluid pressure was normal. Globulin was negative and total protein was 59 mg. per cent. Only two white blood cells, lymphocytes, were found.

The patient was then transferred to Lawson General Hospital on December 19, 1945. Upon admission, he continued to show ataxia and in-co-ordination, progressive weakness of the legs, and complete loss of deep sensibility. On January 14, the spinal fluid showed 128 mg. per cent total protein, with a gold curve of 3322-100000; globulin was negative and there were 3 lymphocytes. All other laboratory studies were within normal limits.

As the case progressed, further studies were obtained, and an alert ward man stated that he was afraid that the soldier was suffering from a kidney disease because his urine was very dark red. This led to further investigation, and the urine was found to be positive for hematoporphyrins. Uroporphyrin and coproporphyrin were negative. Gastrointestinal examination was negative. Throat and stool culture were negative.

Upon admission to the hospital, the patient was mentally somewhat confused. He complained of hearing voices. He showed tremor of the face and hands, had feelings of insecurity, and manifested evidence of fear. Because of some of his reactions, it was thought that he might be suffering from an acute schizophrenic reaction, and confinement on a closed ward was felt to be advisable. After about a week, the period of confusion and incoherence gradually subsided, and he was released to the open ward. His mental reaction was apparently acute, and presented a crescendo and diminuendo pattern. The dark urine was discovered at the height of the psychotic episode and at no other time. Porphyrins in the urine have subsequently remained negative.

Comment

Two cases of infectious polyneuritis and two cases of neuritis secondary to porphyria have been presented. With respect to the neuritis, the two forms are essentially identical, but there are otherwise certain fundamental and distinct differences

Infectious polyneuritis, on the one hand, probably results from a virus infection. It follows, after some delay, acute upper respiratory infection. It occurs in an otherwise healthy individual and may be sporadic or epidemic. The neurologic signs are referable to both the sensory and motor peripheral nervous systems. There are few general systemic manifestations. Hereditary and familial factors are absent. The disease is self-limiting and prognosis is good. Complete recovery may be expected in 75 or 80 per cent of cases. Albuminocytologic disassociation in the spinal fluid is common but is not always present and porphyrins in the urine are invariably absent.

Porphyria, on the other hand, is a familial hereditary disease, resulting in the production and secretion of abnormal porphyrins. There is a long-standing family and personal history referable to the gastrointestinal and nervous systems. There are ill-defined and unexplained episodes of nervousness, irritability, insomnia, transitory blindness, abdominal cramps, and constipation. The neurologic signs are referable almost exclusively to the peripheral motor nervous system; however, some cases may show sensory deficits. Mental symptoms, such as organic delirium, depressions, disturbances of mental content, may be prominent during an acute episode. In the spinal fluid, the albuminocytologic disassociation is seldom noted, but occasionally does appear. Prognosis is grave, and 80 per cent of those affected are expected to terminate fatally.

Other conditions to be differentiated from both diseases are hysteria, poliomyelitis, multiple sclerosis, progressive atrophy, periodic family paralysis, diphtheritic polyneuritis, tic paralysis, serum paralysis and parotitic paralysis.

In discussing the four cases which have been presented, we have the first two which showed fairly clearly the Guillain-Barré syndrome with the classical albuminocytologic disassociation. The third case was unequivocally an acute porphyria with positive clinical and laboratory proof.

In the fourth case, the diagnosis of porphyria was made for the following reasons: The family and previous personal histories were filled with psychogenic manifestations of the type described by Roth.[14] From the history of recurrent colic, the sudden onset of unexplained neuritis and psychosis, and the fact that at the height of symptoms the urine was wine-colored and contained abnormal quantities of hematoporphyrins, it is felt that a diagnosis of porphyria, though not absolutely proved, was undoubtedly justified because of strong presumptive evidence.

Summary

In conjunction with a brief review of the literature, two cases of infectious polyneuritis and two cases of porphyria were presented. They have been differentiated clinically. A diagnosis was made in the fourth case on the basis of clinical manifestations, in spite of the fact that absolute laboratory evidence was lacking.

It is felt that in instances of multiple neuritis, porphyria should be kept in mind and carefully differentiated from other forms of neuritis, especially the Guillain-Barré type, because of the ultimate serious prognosis in porphyria. A diagnosis of porphyria in the absence of excreted porphyrins may be made with reasonable accuracy from clinical signs and symptoms.

THE PRESENT SOUTHERN MINNESOTA MEDICAL ASSOCIATION

(Continued from Page 158)

grams too elaborate to serve the purpose for which the organization had been formed. It was also apparent that, to some extent, it was duplicating the functions of other organizations, such as the state medical association and the tri-state association. The trend of thought among the members was in favor of smaller and more simple meetings, such as those of more recent years, since such meetings permit closer association of the members and more individual participation in discussion.

The primary object of the organization has been improvement of the practice of medicine through dissemination of medical knowledge. In this, it has been eminently successful. Of equal importance, although perhaps intangible, has been the inspiration members have derived from acquaintance with others whose problems and aspirations are identical with their own. I think that all old members will agree that the association has been invaluable in furthering this acquaintance and fellowship.

INDUSTRIAL INTEGRATION

ALBERT E. RITT, M.D.
Saint Paul, Minnesota

THOSE of us engaged in a part-time or full-time industrial program, during the war, and because of it, were placed in unusual and strained positions. As a result we were forced to "streamline" many of our routine industrial procedures. It was expedient and extremely workable to place much of the preplacement physical examination in the hands of a competent nursing staff. This, when properly supervised, resulted in a program that was satisfactory, particularly in view of the demands made by industry for an ever-increasing rate of employment. Inasmuch as the rate of "hired-to-terminated" is still high, our "streamlined" program is still much in vogue.

The completeness of a physical examination need not be judged by the amount of time a medical examiner spends with the applicant for a job. It makes little difference who asks the questions, be it doctor, nurse, social worker, or clerk, provided the information gleaned is negative. In cases where the information is of a positive nature, it then becomes the duty of trained personnel to determine the cause and ultimate effect on industry, if said individual becomes placed in industry. Suppose, for example, the applicant states in his application blank that he is short of breath. It then becomes the duty of the interrogator or the medical examiner to determine whether this is due to some peculiarity of anatomy, i.e., hunchback with a marked scoliosis; congenital or acquired cardiac pathology, e.g., rheumatic heart in a young individual, or heart muscle failure due to arteriosclerosis in an older individual; metabolic, such as one might find in a condition of overweight or hyperthyroidism; infectious, such as tuberculosis of the lungs; or, nutritional or emotional fatigue due to faulty dietary habits, shock, or overwork.

What we, as medical examiners, must attempt to do are the basic, indispensable procedures. These programs should not be intended to reject the handicapped or submarginal worker; rather, to suit the worker to his most productive job in industry and to minimize the defects that the worker will attribute to industry when this tremendous program once begins to be dismantled. It then becomes the duty of the industrial physician and surgeon to learn to safeguard the worker in industry from machine and material hazards; to supervise environmental working conditions; to conserve health and preserve workability of the employe while at work; to restore speedily and properly the injured worker to his former earning capacity; and to be a sympathetic yet unbiased appraiser of the amount of an industrial disability, being neither for the employer nor against the employe. In this position, the surgeon becomes a sort of liaison officer between the worker and his job, and thereby attempts to atttain 100 per cent efficiency with a minimum amount of risk and time lost.

It is particularly advisable at this time when the relationship between the so-called "plant doctor" and the injured employe is more than ever likely to be strained, to redouble the effort to bring the worker, management and the doctor closer together. In order better to accomplish this, it is the duty of the medical department to strive to foster that feeling of confidence between the staff and the worker to such a degree that there will be no doubt in the mind of the worker that nothing is left undone to speed the progress of his return to his former earning capacity. As a further aid in this direction, it is the duty of the industrial organization to provide a competent and well-trained medical and nursing staff, one that becomes known for its ability to carry out with dispatch the duties for which it has been created. To this end, also, there must be sponsored a much closer co-ordination between the industrial and the private physician. It is fully realized that a system in industry can never be devised to supplant the duty of the private physician. No matter how much industry attempts to give the worker, it will be accused of cutting corners or being incomplete. Before this can anywhere near be accomplished, the worker must divorce from his mind the idea of the "plant doctor" as a disinterested physician. The worker must be made to feel that the physician has his interests at heart—that it is the worker who is the backbone of the organization.

Preplacement examinations are made to facilitate orientation and advancement of the worker in accordance with his own physical and mental status; to acquaint him with his own physical shortcomings; to guide him in improving and maintaining good health; to safeguard the health and safety of his associates; to discover and to control unhealthful exposure; and to assist in directing the below-par or sick individual into the hands of conscientious medical assistance. As such, the examination must be accurate in appraisal, unprejudiced in evaluation, and personal in principle. The question naturally arises as to the ability of the average worker to select a physician either to examine him preparatory to work or to treat his industrial ills. True, the worker has unlimited confidence in the physician of his own choosing, and if he can only be made to appreciate the effort behind the so-called "plant doctor," his familiarity with the operation of the plant and materials involved, and the frequency with which he sees the same or similar situations repeated, he then, and then only, can begin to appreciate that perhaps the "plant doctor" is, by virtue of all this, somewhat better equipped to treat and handle industrial ills. Further, the industrial physical examination is not intended to be compared with the examination given in private practice. Each has its purpose. The worker must also understand that in industry he has the right of appeal to his own physician. This should be encouraged rather than denied.

When one considers that maladjustment in industry ranks along with accidents and discordant interpersonal relationships in creating absenteeism, inefficient work, and low morale, it is easier to understand why management might do well to insist on proper placement in industry. This fact takes on added importance when one further considers that the average man loses 0.6 day per annum from occupational causes as against 8.8 days per annum from non-occupational causes. Multiplying this figure by upward of fifty million people employed, one readily arrives at the staggering figure of lost production and lost time. In 1942 nearly four billion dollars were spent because of illness and disability. This figure was slightly less than 4 per cent of the total national income.

In setting up a physical examination program with all of its restriction, industry is confronted with four possible situations.

1. There are a sufficiently large number of employes seeking employment so that industry may be selective, selecting from only the comparatively small percentage of physically perfect applicants.

2. Industry needs manpower to the point of hiring some one for the job, with little regard for defects.

3. Industry may try to be ultra-efficient and set up a physical replacement examination that loses itself in a multiplicity of wasted effort and motions.

4. Industry may try to be practical, yet effective, in uncovering defects of body and mind so that neither the employe nor the employer is penalized.

Obviously, Group 1 is neither feasible nor practical, nor is it a sign of effective preplacement interviewing. Yet unless the industrial commissions and industry get together it is that group to which industry will turn in an attempt to protect itself. In so doing, society will bear the burden of unemployment and employment costs, and this again in turn will be reflected in terms of higher merchandise prices paid by the consumer.

Likewise, Group 2 is far from the answer; and yet there are individuals in this group who can be suited to industry.

Group 3 takes on the duties of "Mr. Citizen's private physician, and as such should not come under the scope of industrial or preventive medicine.

Group 4 then becomes the logical alternative. Even here, one must learn to discriminate between the prospective employe (the applicant) and the one already employed. It is the industrial physician's job to do those things listed elsewhere in this paper. Proper preplacement interviewing by trained workers therefore bridges one of the large gaps in the industrial medical program.

Mantoux testing is valueless unless correlated with an x-ray examination (approximately 60 per cent of the adult population is Mantoux positive). Wassermann testing is of value in bringing to the fore the case of syphilis that is unknown to the individual. It protects neither the individual tested nor the employer and unless repeated may lull the patient into a false sense of security.

In the light of the above there are certain functions that are *musts* from the physician's standpoint. He must evaluate:

CLINICAL-PATHOLOGICAL CONFERENCE

EPITHELIAL NEOPLASMS OF THE APPENDIX

ARTHUR H. WELLS, M.D., and HAROLD H. JOFFE, M.D.
Duluth, Minnesota

Dr. A. H. Wells: We wish to present briefly four cases of epithelial neoplasms of the appendix and discuss the associated terms of carcinoid, mucoid carcinôma, adenocarcinoma, adenoma, pseudomyxoma peritonei, and mucocele of the appendix.

Case Reports—Clinical Aspects

Dr. S. W. Arhelger: (Case 37141) This eighty-three-year-old retired housewife had been suffering with pain about the umbilicus of two days' duration. The pain moved to the hypogastrium and later became constantly severe and localized in the right lower quadrant. She had vomited greenish material once and had noticed mild constipation. Her past history included hospitalization ten years ago for longstanding severe hypertensive cardiovascular renal disease and toxic nodular goiter. Her blood pressure at that time was 224/122. At the time of the last admission it was 180/100; pulse, 120; respirations, 14; and temperature, 100.4° F. There was severe tenderness and rebound tenderness with moderate muscular spasm in the right lower quadrant. She also had percussible enlargement of the heart to the left and a systolic mumur, which was maximum at the apex and transmitted to the left axilla, but no pulmonary râles. The white blood cell count was 12,700 with 74 per cent neutrophiles. Her blood urea and creatinine and urinalysis were essentially normal. An emergency appendectomy was followed by an uneventful convalescence. No further operation was considered advisable.

Dr. L. L. Merriam: (Case 3038) This sixty-eight-year-old housewife claimed some abdominal discomfort since childhood. She had been admitted to the hospital one year before her death with blood in her stools, at which time small ulcers in the rectum were described as the source of the blood. Eight weeks before her last admission and three months before her death, she had an attack of abdominal cramps and diarrhea. She noticed loss of weight, poor appetite, abdominal "bloating," and belching. On admission, 4,750 c.c. of ascitic fluid was removed from her distended abdomen. Carcinoma cells were found in this fluid. She became gradually weaker during her last two months.

Dr. W. N. Graves: (Case 26912) This thirty-seven-year-old forester suffered from pain in the right side of the abdomen for twenty-four hours. It began at the time of a long auto ride over a rough road. The pain was aggravated by walking, and his abdomen became sore. Physical examination revealed muscular spasm and tenderness in the right lower quadrant of the abdomen, and tenderness to the right on rectal examination. He had a white blood cell count of 15,000 with 70 per cent neutrophiles and a temperature of 98.4° F. An appendectomy was followed by a rapid return to normal activity.

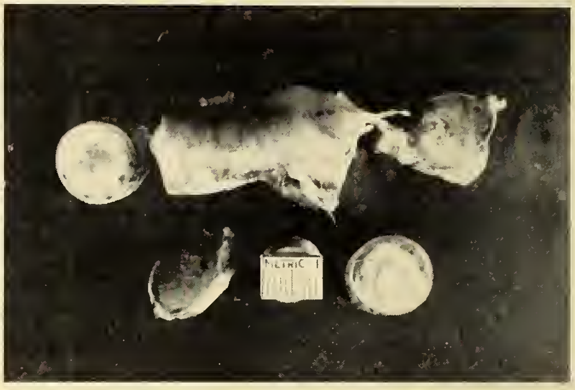

Fig. 1. Serosal and cut surfaces of an appendix with mucoid carcinoma.

Dr. A. N. Collins: (Case 37213) This twenty-one-year-old steelworker had a steady dull pain in the lower right quadrant of the abdomen for forty-eight hours. Physical examination revealed mild tenderness in the same area of the abdomen, and his white blood cell count was 13,850. An emergency appendectomy was followed by a rapid convalescence.

Pathological Aspects

Dr. A. H. Wells: (Case 37141) This appendix (Fig. 1) measured 7 cm. long and from 1 to 1.5 cm. in diameter. There was a perforation, 4 mm. in diameter, at the distal end at a localized site of suppuration. The remainder of the lumen was filled with mucus-forming anaplastic epithelial cells (Fig. 2) which invaded the muscularis. At the proximal end the mucosal glands had a papillary adenomatous alteration without invasive properties.

(Case 3038) There was a rather highly anaplastic adenocarcinomatous infiltration (Fig. 3) of the walls of a swollen (1 cm. in diameter, 6 cm. in length) appendix, with an obliterated lumen and an irregular distribution of muscle fibers suggestive of a congenital

anomaly of the appendix. The malignancy had extended to regional retroperitoneal lymph nodes and both peritoneal and pleural surfaces. Terminally, she developed intestinal obstruction due to malignant adhesions about loops of small intestines.

(Case 26912) This man's appendix had small clumps of highly hyperchromatic, uniformly small, epithelial cells (Fig. 4) with both simple glandular arrangements and small clumps with palisaded peripheral cells. These carcinoid cells were located primarily in the obliterated lumen of the distal 1 cm. of the appendix, and a few cells had extended into the muscularis. In addition, the proximal appendix had a very mild neutrophilic infiltration of all layers.

(Case 37213) This appendix, 7 cm. in length and 0.7 cm. in diameter, had no unusual gross appearance. However, histologic sections from near the middle revealed a small area of mucosa with a slightly papillary adenomatous proliferation of the mucosal glands, of neoplastic proportions without malignant invasion (Fig. 5). There was no inflammatory change.

In conclusion, these four cases are illustrative of different forms of epithelial neoplasms of the appendix: mucoid carcinoma, adenocarcinoma, carcinoid, and adenoma.

Carcinoid

Although there is no general agreement as to classification of epithelial malignancies of the appendix, it is obvious that carcinoids (enterochromaffin, basi-granular, Nicolas, Kultschitzky, Schmidt and Ciaccio cell tumors) should be set in a class by themselves. They have been described as often as one in every 200 appendectomies[4] and have been studied in great detail, so that the practical aspects of their nature are well known. Carcinoids are found 50 per cent of the time in the appendix, and the remainder in the ileum, jejunum, stomach, gallbladder, duodenum, Meckel's diverticulum, cecum, colon, and rectum. They most likely develop from the Kultschitzky cells found sparsely scattered in the bases of Lieberkuhn's crypts along the intestinal tract. The physiologic function of these cells is not settled. It is significant that approximately 25 per cent of the recorded[1,2,11] carcinoids of the small intestines metastasize, and some are the cause of death due to their malignant nature. Nearly all of those found in the stomach and colon tend to metastasize. The same tumor in the appendix is much less likely to extend beyond this organ. Less than twenty had been reported as metastatic by 1942.[5,10] Even when it does reach a regional lymph node, it is very likely to remain there for many years without harm to the patient.[8] Consequently, for all practical puropses, the surgeon can consider carcinoids of the appendix as essentially benign. However, if recognized at the time of the operation, local extensions should be sought for and removed.[5] One should avoid postoperative x-ray therapy and mental disturbances of the patient concerning "cancer."

Adenocarcinoma

Other types of carcinoma of the appendix represent only about 10 per cent of the total malignancies of this organ and are much more serious than the relatively common carcinoids. They are more likely to occur in the fifth and sixth decades rather than in the third, as is the case in carcinoids of the appendix.[6] Unquestionable examples of this smaller group, which is sometimes called adenocarcinoma, are rare and should be reported in the medical literature for future group study, reference, and clarification of the subject. Uihlein and McDonald[14] divide their seventeen cases (from thirty-one years of appendectomies at the Mayo Clinic) into "cystic" and "colonic" types. Although the Lieberkuhn's glands of the appendix undoubtedly have the same potentialities for varieties of epithelial malignancies as the same glands in the colon and rectum, there appears to be a decidedly increased tendency toward mucoid carcinoma in the appendix. These malignant cells form mucin and pseudomucin (chemical and tinctorial variants of mucus).[10] The extension of this malignancy to peritoneal surfaces may lead to pseudomyxoma peritonei or "jelly belly." The abdominal cavity may become filled with gelantinous material.

Benign Epithelial Lesions

Simple mucoceles of the appendix most often result from an inflammatory process obliterating the proximal lumen. Subsequent secretion of mucus by lining epithelial cells in the distal lumen may in time rupture the atrophic appendix walls and produce pseudomyxoma peritonei.[13] The condition can kill as the result of intestinal obstruction.[9] Whether or not this non-neoplastic lesion (mucocele) becomes malignant, as has been theorized,[15,16] needs further confirmation. Furthermore, it may be very difficult to rule out mucoid carcinoma in an apparent case of ruptured mucocele. Pseudomyxoma peritonei is most often due to mucin secreting, benign or malignant ovarian cysts.

It is thought that some of the adenocarcinomas have their origin in benign papillary adenomas of the appendix.[14] There is much proof of this relationship in the colon. Furthermore, the tendency toward multiple papillary areas in the colon makes it imperative that x-ray studies of the colon be performed in patients with adenomas in their appendix, such as in our Case 37213. Benign papillary adenomas may form mucus and distend the appendiceal lumen with this product to the point of rupture. Their differentiation from a low-grade mucoid carcinoma may be extremely difficult, if not impossible.

Clinical Manifestations

"It is futile to attempt to make a preoperative diagnosis" of appendiceal tumors.[12] The odds favoring common lesions with the same manifestations are too great. In a review of ninety-six cases[7] of carcinoma of the appendix, 83 per cent of the patients suffered from symptoms of appendicitis and 28 per cent had symptoms for one year or more. In another report of twenty-eight patients[10] with appendiceal cancer, the chief complaint was pain in the right lower quadrant of the abdomen. The associated appendicitis so frequently found will of course produce all of the signs and symptoms of this disease. Rarely a tumor mass or blood in the stool may be evident.[14] A chronic recurring ill-defined pain in the appendiceal region is a frequently mentioned symptom of carcinoid. In many cases, this lesion is entirely clinically quiescent and is described as an incidental finding in laparotomies performed for other lesions.

Summary

1. We have presented four case studies of patients with different epithelial neoplasms of the appendix, including mucoid carcinoma, adenocarcinoma, carcinoid, and papillary adenoma.
2. A very brief review of the nature and interrelationships of these neoplasms, and of mucocele and pseudomyxoma peritonei, is given.

NOTES ON THE HISTORY OF MEDICINE IN FILLMORE COUNTY PRIOR TO 1900

By NORA H. GUTHREY
Mayo Clinic
Rochester, Minnesota

(Continued from January issue)

A. O. Heiberg, who was born at Christiania (Oslo), Norway, in November, 1855, received his primary education at Quam's Latin School in that city and his more advanced schooling at the Latin School at Trondjem. He was preparing to enter the Fredericiana University to study medicine, but changed his plan and instead took a course of two years at the Stenkjaer Apothecary under Mr. A. J. Hoegh.

In April, 1873, Mr. Heiberg came to America and to southern Minnesota, which was to be his permanent home. In his first year he worked for a druggist, Mr. Pilzer, in Winona, and then settled in Rushford, Fillmore County, where he was associated as a pharmacist in different drugstores, first with K. Olson for four years, subsequently with Elling P. Kierland, a pioneer medical practitioner, and finally with A. E. Hazard, with whom he bought the Corner Drug Store, which the two men operated until the partnership was dissolved by mutual consent in 1902.

On August 30, 1887, in Rushford, Mr. Heiberg was married to Bertha Anderson; five children were born to this marriage.

In 1889, returning to his original intention of becoming a practicing physician, A. O. Heiberg entered Rush Medical College, in Chicago, where he spent two years before going on to the Jefferson Medical College, in Philadelphia; from which he was graduated in 1893. Again in Rushford, the possessor of state medical license No. 346, under the act of 1887, he entered on ten years which brought him deservedly a large and successful medical practice, in which his scientific skill, together with his cheerful manner and sympathetic understanding, won him confidence and esteem. Among his professional affiliations were memberships in the Winona County Medical Society and the Southern Minnesota Medical Association.

When, in 1903, symptoms of bulbar palsy appeared, and skilled physicians in the East told Dr. Heiberg that the months of his life were numbered, he decided to move his family to Northfield, Minnesota, where the children could obtain excellent educational advantages, and he made the change during the early summer. He died in Northfield on March 18, 1904, survived by Mrs. Heiberg and the five children.

About **Ole T. Hoftoe,** little information has come to light except that he was born in New London, Kandiyohi County, Minnesota, in 1854, was graduated from Rush Medical College on February 17, 1885, and within a month, on March 13, received state certificate No. 1012 (R) to practice medicine in Minnesota. For a year or so, in 1885 and 1886, he was resident in the village of Fountain, Fillmore County, and in the next year in the larger, near-by town of Lanesboro. In the following year it appears that he had moved to Dakota Territory (North Dakota) where, on March 30, 1888, Dr. O. T. Hofte [sic] was registered as being in practice in Abercrombie, Richland County, and there, according to a gazetteer and business directory, he remained well into the nineties. After an undetermined period of time, but certainly prior to 1907, Dr. Hoftoe returned to his native place of New London. After 1909 his name did not appear in the official medical directory.

Robert Hoyt, who became one of the earliest of physicians in Fillmore County, was born at Hesper, Iowa. It is said that soon after his graduation in medicine, probably in 1859 or 1860, he settled in the village of Lenora, and there for two years was a confrere of Dr. James M. Wheat, who had come in 1856. From Lenora he moved to Beloit, Wisconsin, the home of his wife's parents, where he followed his profession for many years. In an early history of Fillmore County he was mentioned, it is believed erroneously, as a charter member of the Fillmore County Medical Society, which was founded in 1866.

Robert W. Hoyt, almost certainly a relative of Dr. Robert Hoyt, the pioneer physician already mentioned, was born at New Haven, Addison County, Vermont, on February 14, 1852. When he was eight years old he moved with his parents to Fillmore County, Minnesota, where he spent his boyhood and attended the local schools. In 1875 he was graduated from Rush Medical College of Chicago and immediately afterward began to practice medicine in the community of Lenora. It is said that in the next year he moved to Walnut Grove, Redwood County, where he remained for a considerable number of years, into the eighties. In June, 1880, he was married to Myra E. Tester, of New Lisbon, Wisconsin. By 1890, Like Dr. Robert Hoyt before him, Dr. Robert W. Hoyt had moved to Wisconsin, the home of his wife's people, and was established in medical practice in New Lisbon, where he still was in 1912; his name did not thereafter appear in the medical directories.

Dr. Huffman, apparently a medical nomad, was in Preston early in 1863, exhibiting, according to the *Preston Republican,* "much skill in the way of restoring loss of sight and hearing. Those afflicted with diseases of the eye and ear would do well to call at the Minnesota House and consult him." Another clue to this practitioner lies in the statement that Dr. Huffman, an eye and ear specialist from St. Louis, practiced in Austin, Mower County, for a few months in 1863.

Thomas W. Hunt, a graduate of the Jefferson Medical College in 1894, was licensed in Minnesota on July 10, 1894, receiving certificate No. 456, under the "Act to Regulate the Practice of Medicine in the State of Minnesota" as approved in 1887. He was then a resident of Douglas County. Not long afterward he presented his license in Fillmore County, and in the issue of 1896-1897 of a state gazetteer and business directory he was listed as being in practice in Lanesboro. In the official register of physicians of Minnesota of 1883-1909, his name appeared without post office address. His name was not included in the first (1907) issue of the directory of the American Medical Association.

Johan Christian Hvoslef (sometimes seen Hooslef), who became one of the distinguished citizens and physicians of Fillmore County, was born at Førde, Søndfjord, Norway, on August 24, 1839, a member of a family which gave several outstanding men to the political and professional history of Norway.

Well-trained in academic subjects at the Latin School and in general sciences at the University of Norway, both at Christiania, Johan C. Hvoslef came to America in 1872 and continued his studies at Rush Medical College, from which he was graduated in 1876. In the same year he was married to Karen Anderson of Wisconsin and came with his wife to Lanesboro, then a village of about 1500 people, where he lived and continuously practiced his profession until his death on October 11, 1920. Dr. and Mrs. Hvoslef had one child, a daughter, who died in Lanesboro at the age of six years. Dr. Hvoslef was survived by his wife and his sister, Mrs. Thorvold Klavanae, of Christiania. A brother, Nils C. V. L. Hvoslef, a state official of Trondjem, Norway, had died earlier.

Dr. Hvoslef's life in Lanesboro was that of the country doctor, able, faithful, overworked, unsung. It is a matter of record that in 1882, working with the State Board of Health, Dr. Hvoslef as health officer dealt efficiently with the local outbreak of smallpox. Under the Medical Practice Act of 1883 he received state certificate No. 466 (R) on December 28, 1883, which he filed in Fillmore County on October 28, 1889. He was a member of the official local and state medical societies and of the American Medical Association.

A quiet, modest, retiring man of distinguished ability, Dr. Hvoslef was not so well known in the state as he should have been. Besides being a skilled physician and surgeon who served his community well, he was a naturalist of distinction. Thomas S. Roberts, M.D., in his masterly work, *The Birds of Minnesota,* recognized Dr. Hvoslef's ability as a physician and paid tribute to him as a naturalist:

> Perhaps no one man did so much to develop a knowledge of the bird-life of a single locality in the state as did Dr. Johan C. Hvoslef. . . . He was a well-trained man and, possessing an intense interest in natural history and a methodical and painstaking type of mind, he was well fitted to make an intelligent, careful study of the region in which he passed the greater part of his life. Throughout the entire fifty-four years, he kept a detailed diary in which he recorded all his observations, covering the whole field of natural history, though birds and plants were his first interests. There are fifty-four volumes of these journals, with three additional general notebooks. The year following Dr. Hvoslef's death, Mrs. Hvoslef very generously presented, in complete form, this life-work of her husband to the Museum, where it is now one of the most valued possessions. Dr. Hvoslef, during his life, had given to the Museum his collection of bird-skins, numbering some four hundred, and after his death, his wife donated a small collection of birds' eggs, among which were those of the blue-winged warbler, unique specimens for Minnesota.
>
> No part of these diaries have ever been published, but from them were taken the bird-migration records that Dr. Hvoslef sent to the United States Biological Survey at Washington over a series of years, and concerning which Mr. Wells W. Cooke, in one of the Survey bulletins, stated that the information from Lanesboro was the most satisfactory that had been received from any source. There is also on file at the Museum a considerable series of letters from Dr. Hvoslef, relating almost entirely to the bird-life of Minnesota, received by Thomas S .Roberts, M.D., Fellow of the American Orinthologists' Union, Professor of Orinthology and Director of the Museum of Natural History of Minnesota. Dr. Hvoslef's great modesty prevented his publishing at first hand the results of his work. This explains the absence of his name from the Minnesota bibliography. But he generously and freely supplied information to others, and thus he is quoted, second hand in many connections, as authority for original and valuable records. All the records from Lanesboro in this work

are from Dr. Hvoslef's work. Fortunately he recorded carefully and accurately everything that came under his notice, and the Minnesota bird-students owe no small debt of gratitude to this retiring but accomplished and hard-working man of science.

George E. Jackson for many years a practicing physician of Minnesota, was a graduate of Rush Medical College in 1880, and under the Medical Practice Act of Minnesota of 1883 received state certificate No. 9 (R) on October 11 of that year. He then was living in Fergus Falls, in Otter Tail County. Strangely, it has been impossible thus far to discover more than isolated bits of information concerning this well-qualified physician.

On June 9, 1885, George E. Jackson, M.D., a graduate of Rush on February 20, 1880, registered in Dakota Territory as in practice at Lakota, Nelson County; during his residence in Dakota he was appointed County Superintendent of Health.

Dr. Jackson returned to Minnesota probably in the late nineties, and by 1899 he had settled in Chatfield, Fillmore County; in that year at a meeting of the Southern Minnesota Medical Association in Owatonna, in Steele County, he was elected to membership. Dr. Jackson remained in Chatfield at least into 1912. His name did not appear in the issue for 1914 of the directory of the American Medical Association.

Charles H. Jacobson was born in Norway on May 17, 1856, received his early education in the schools of his native place and, in 1871, at the age of fifteen years, came to America and settled in southern Minnesota. After working for five years in the drug store of Albert Weiser in Preston, he decided on the study of medicine and entered the Bennett Electic College of Medicine and Surgery, from which he received his degree of doctor of medicine in March, 1879. Immediately after his graduation, Dr. Jacobson improved his medical knowledge by taking a special course at the Chicago College of Ophthalmology and Otology before returning to establish himself as a physician in Preston. In 1881 and 1882, at least, he was in active practice, and that he used his specialty is evidenced by the following item in the *National Republican* of Preston of December 29, 1881: "Lost by Dr. Jacobson: A myopodiartotican, used in cases of myopia."

The fact that, subsequent to 1883, Dr. Jacobson's name did not reappear in the state gazetteer which had carried it previously is inconclusive evidence that he had gone elsewhere. It is significant, however, that he was not listed in the official directory of physicians in Minnesota of 1883-1890, nor in the edition next following.

J. Ross Johnson was born on July 18, 1855, at Oak Leaf, Ontario, Canada, the son of Mr. and Mrs. Samuel Johnson, who were farmers. In 1883 he was graduated from the Medical School of McGill University, and shortly afterward came into the Middle West of the United States, to settle in Spring Valley, Minnesota, at the suggestion and request of friends from Canada who already had established themselves in that community. On October 13, 1883, under the new Medical Practice Act of the state he received license No. 150 (R). That he at once identified himself with the medical profession of the state is evidenced by his election to membership in the Minnesota State Medical Society at the annual meeting held at Minneapolis, in Market Hall, on June 19, 1883. At this same meeting, one of his senior colleagues, who had been in Spring Valley since 1871, Dr. Russell L. Moore, became third vice president of the association. Dr. Johnson allied himself with the local group of physicians in Fillmore County and, in 1904, on organization of the Houston-Fillmore County Medical Society, became an active member.

J. Ross Johnson was married on August 30, 1882, to Jennie Green, a Canadian, and brought his wife with him to Spring Valley. They had three children, Florence, Charles Harcourt, and Harry H. Johnson. When Mrs. Johnson died in 1894, her body was taken back to Canada for burial. In 1897 Dr. Johnson was married to Martha Banks; there were no children of this marriage.

Dr. Johnson belonged to a family of which two other members who were physicians came into southern Minnesota. His brother, Dr. Charles Harcourt Johnson (1859-1917), newly graduated from McGill University, settled permanently in Austin, Mower County, in 1884. His half-brother, Dr. William Nassau Kendrick (1872-1936), also a graduate of McGill, in 1896, in that year began practice with him in Spring Valley; from 1898 to 1905 Dr. Kendrick was in Austin in partnership with Dr. C. H. Johnson, but in 1905, on the death of Dr. J. Ross Johnson, he returned to Spring Valley to carry on his half-brother's practice.

Dr. J. Ross Johnson is recalled as a fine man and citizen, a physician and surgeon of unusual knowledge and skill, whose favorite diversion was fishing and whose love of horses was a distinguishing quality. In those pre-automobile days, he kept, like many of his confreres, from six to eight excellent driving horses most of the time, and although he drove them hard, he handled them with skill and consideration and gave them the best of care. Only ten days before his death in February, 1905, he drove sixty miles in a cutter.

His son, Dr. C. H. Johnson, has recalled that Dr. Johnson in his heavy and widespread practice used to consult on occasion with his near-by colleague, Dr. Albert Plummer, of Hamilton (later of Racine), and that he was "a great admirer" of Drs. William J. and Charles H. Mayo, who sometimes were called in consultation into the community.

The death of Dr. Johnson on February 27, 1905, at the height of his usefulness, was a sorrow and loss to Fillmore County. Dr. Johnson was survived by his wife, who in 1943 was living in Austin, Texas; by his two sons, Harry H. Johnson, a jeweler of Spring Valley, and Charles H. Johnson, who has been a physician since 1912, in Spring Valley since 1916; and by his daughter Florence (Mrs. Claude W. Rossman, of Minneapolis). Mrs. Rossman's death occurred in the nineteen thirties.

In speaking of his father, Dr. Charles H. Johnson commented on the advances and conveniences in medical practice of later years of which the older man could not know. In his times calories and vitamins were not recognized factors in nutrition, the value of roentgen rays in medicine had not been fully realized, and the sulfa drugs were unknown. "It seems too bad that he was born too soon and died at the age of forty-nine, just a young man."

Henry Jones was born on March 13, 1845, on a farm near Nashville, Ohio, the son of William Jones, who was of Welsh blood and a native of Steubenville, Ohio, and Sarah Collier Jones. His mother was descended from an English family who had come to America early in the eighteenth century; her grandfather twice was sent to Congress from Ohio when the state was young. Henry Jones had seven brothers and sisters: William, Sylvester and

Samuel, Mollie Wright, Sue Rose, Elizabeth Hunter and Evangeline (Mrs. Warner, of Morrison, Illinois, the only member of the family living in 1941).

Henry Jones grew up on his father's farm, receiving his early education in the schools of Nashville. In his nineteenth year he enlisted in Company B of the Sixtieth Ohio Regiment of Volunteer Infantry and with it served at the front until he was wounded at the battle of Petersburg; on his release, after ten months in a hospital in Philadelphia, he received his honorable discharge from the army and returned home. Before continuing his formal education, he worked for a time, loading lumber on the first trains to pass through Ohio. During 1866 and 1867 he was a student at the Franklin Institute in Prophetstown, Illinois, and for a year studied medicine under Dr. J. H. Mosher of that city in preparation for enrolling at Rush Medical College in 1869. Graduated from Rush in February, 1871, he began his medical career in the village of Granger, Bristol Township, Fillmore County, Minnesota, but in September of the following year, because of superior financial opportunity, he moved to the larger place of Preston, in Preston Township. He was succeeded in Granger by Dr. Don J. Lathrop, who arrived in the spring of 1872. In Preston, Dr. Jones remained in active practice for forty-six years, during which he numbered among his fellow physicians Lafayette Redmon, James H. Phillips, John A. Ross, Lyman Viall and George A. Love, as well as many others who came and sooner or later passed on. And during these years, like all the other physicians of the period and region, he met the discomforts and hazards of carrying on a country practice in all weathers and over all roads. Excerpts from old records and newssheets give glimpses of him at work: assisting Dr. Ross "in the presence of Mr. Love, a medical student," to perform an autopsy on the body of a child who had died from cerebrospinal meningitis; refusing, after he had been called on a case which proved to be one of smallpox, to see other patients or to appear in public until danger of conveying the disease to others had passed; performing an operation, with Dr. Lathrop, for removal of a ruptured eyeball, under chloroform anesthesia, on an old gentleman who lived near Granger.

On December 24, 1874, Henry Jones was married to Bertha A. Loomis of Preston. The only child of the marriage, Charles Henry, died in infancy; Mrs. Jones died in 1878. Dr. Jones in 1881 was married to Ella Gray of Decorah, Iowa, and to this marriage were born three children: Mabel, who died young; Rodney C., who became a musician, at one period living in Wallace, Idaho, and in later years in Minneapolis; and Millie M. (Mrs. I. Kasten, of Chicago).

In 1882, to meet the conditions of practice of the times, Dr. Jones took up the study of dentistry and thereafter was both dentist and physician, but especially dentist. There were many items in the local newspaper of those years which mentioned his skill and fine equipment or which stated that Dr. Jones, Preston's popular dentist, had just returned from a successful tour and would remain in his home office for about two weeks.

On December 31, 1883, under the new ruling of medical practice in the state, Dr. Jones received certificate No. 668 (R). From 1872 to 1877 his professional card appeared in *Western Progress*, the newspaper of Spring Valley, as well as in the local papers, and his name was listed in Polk's gazetteer almost continuously from the late seventies for many years. From January 6, 1889, to January 6, 1891, he was coroner of Fillmore County.

President's Letter

Physicians Obligated to Remedy Conditions in State Institutions

THE responsibility for the health of the citizens of Minnesota rests squarely on the shoulders of its physicians, and it is the purpose of every member of the Minnesota State Medical Association to discharge this obligation in an efficient, humanitarian and ethical manner. We take pride in the standards of medical care in rural and urban communities. We are proud of our state program for the control of contagious disease, of our public health activities, of our record in the military service and at home during the war. However, in one field, one in which we find the largest number of patients, conditions exist which are far from desirable. I refer to the mentally ill who inhabit our state institutions and who constitute a profound responsibility of the physicians as well as of other citizens of the state.

More than 50 per cent of hospital beds in Minnesota are occupied by patients who suffer with mental disease. Such patients in the state reach the astonishing total of almost 11,000, and in this number are not included those individuals who are registered in the school for the feeble-minded at Faribault and the epileptic colony at Cambridge. The fact that these individuals represent such a large proportion of the families of the state proves that care of the patients in many instances constitutes a serious social problem.

The publicity which recently has been directed against certain hospitals for patients suffering with mental disease has aroused much adverse criticism. It should reveal the great responsibility which falls on all reliable citizens of this nation. In physical equipment and proportionate size of professional staffs, Minnesota institutions compared favorably with those of most other states twenty years ago, but this condition does not exist today. No longer can we coast along on such an illusion. There is more good fortune than merit in the fact that the institutions of this state escaped the humiliating glare of recent investigations.

A survey of state hospitals conducted in 1939 and 1940 revealed that too few physicans were engaged in caring for patients suffering with mental disease. Specifically, it was learned that in Minnesota there was only one physician for every 435 patients in our state institutions. At this time I believe that the national average is one physician for every 250 patients. The ratio of attendants and ward personnel in 1940 was one for every fifteen patients. The standard approved by the American Psychiatric Association is one physician for every 150 patients and one attendant for every 5.6 patients.

The responsibility for these conditions is not that of the superintendents of the institutions. I am reliably informed that the service which they have rendered, with their limited professional and attendant staffs, has been heroic. This is especially true in Minnesota where problems have been presented to the legislature repeatedly through the Director of Public Institutions, who acts as the intermediary agent of the superintendents of the institutions. Their requests for facilities sufficient to insure standard, adequate care of their patients often have been sidetracked until other demands have been satisfied, and what has been left of the budget has been sufficient to afford only a custodial level of patient care. Minnesota now ranks very low among the states of the nation in per capita expenditure for the mentally ill.

Apparently, the chief interest evinced by our legislature has been in the housing of patients. Undoubtedly, this phase of the problem has been, and is, serious. Today almost 11,000 patients are crowded into space which originally was intended for not more than 8,000. In certain institutions, overcrowding runs as high as 30 per cent and conditions exist which run counter to regulations of the State Fire Marshal as well as those of the State Board of Health. These statements are no doubt unpalatable, and what makes them peculiarly so is the fact that it is impossible to refute them.

In spite of the obvious need for funds for physical equipment, I doubt that this phase of the problem is nearly as serious as that which exists because of lack of other facilities for the care of patients. Measured in terms of human values and in the light of our responsibility to the citizens of the state, we have a great duty. We must provide adequate programs of therapy in order that patients may be returned to productive life. We must use every means to prevent recurrence of illness and to provide facilities for counsel and guidance in order to prevent the development of additional mental disorders in the community.

It is important that conditions pertaining to a form of illness which afflicts half the patients in hospitals of the State of Minnesota should be understood by our legislators. If these patients are to receive adequate medical care, the cost during the next few years will be great. It should be great. It is a justifiable expense. It is an appalling fact that the per capita per day cost in our state institutions barely exceeds one dollar. It is almost unbelievable. The standards set up by the American Psychiatric Association are $5.00 per capita per day for patients who suffer with acute conditions and $2.50 per capita per day for those who are chronically ill. Evidently, these facts are not well known to our legislators. It is the responsibility of the physicians of the state, as well as of other responsible citizens, to make it known that our goal is adequate treatment and comfortable housing for every patient in our state hospitals for the mentally ill. This must be done without further delay, in order that we may look forward to a decreasing, rather than an ever-increasing, custodial population in our state hospitals.

Louis a Buie

President, Minnesota State Medical Association

HISTORY OF MEDICINE IN MINNESOTA

(Continued from Page 184)

Dr. Jones was an independent voter, was well read and tolerant. He was a member of the Presbyterian Church; of the Underwood Post No. 122 of the Grand Army of the Republic, and its commander for many terms; of the Independent Order of Odd Fellows and of the Masonic Blue Lodge of Preston, the latter of which he joined on December 17, 1873. An avocation which he made profitable for a number of years was the keeping of bees.

After forty-six years in Preston, "highly esteemed . . . respected for his virtues, attainments and labors," Dr. Jones moved to the town of Bethel, Anoka County, where he practiced medicine six years before retiring to California to make his home. He died in Monrovia on June 30, 1931, from the infirmities of old age. Mrs. Jones survived him, and until her death, on February 3, 1943, at the age of eighty-five years, resided with her daughter, Mrs. Kasten, in Chicago.

About **J. R. Jones** only one note has been gleaned. In an historical atlas of Minnesota, of 1874, of which he was a patron, there appears the entry that J. R. Jones was a physician, was born in Monroe County, New York, came to Minnesota in 1861, and in 1874 (and earlier, obviously) was living in Lanesboro, Fillmore County.

Of the career of **Emma Adeline Keeney** only an outline is presented. Emma Adeline ——— was born in 1876 (the surname is lacking, as is the date of her marriage). She was graduated from the College of Homoeopathic Medicine and Surgery of the University of Minnesota in 1897, and in April of 1898 received her license to practice in the state. There is evidence that she began her professional career in Spring Valley, Fillmore County, and practiced there for possibly a year; in a business directory of 1898-1899 appeared the name of "Mrs. E. A. Keeney" in the list of physicians of the town.

From Spring Valley Dr. Keeney moved to Austin, Mower County, where for a time she was in partnership with Dr. Fannie K. Fiester, who in 1893 had been graduated from the Woman's Medical College of Northwestern University. Evidently desirous of improving her professional knowledge, Dr. Keeney took graduate work, and in 1904 was graduated from the Hering Medical College of Chicago. Presumably she settled soon afterward in Albert Lea, Freeborn County, where she was practicing in 1907. In 1909 she was licensed to practice in the state of Oregon, and into 1914, after which further entry did not appear, she was in active practice in The Dalles.

STREPTOMYCIN

STREPTOMYCIN is now available to the profession, and reports indicate its great value in a limited number of infections. Its high cost will necessarily limit its use. The fact, too, that various strains of the same bacterial species differ widely in their sensitivity to streptomycin, and that its absorption by individuals differs so greatly, has made evaluation of its usefulness difficult.

Streptomycin has been found of value in the treatment of a number of infections due to both Gram-negative and Gram-positive bacteria. Perhaps the most important are urinary tract infections due to Gram-negative organisms, infections due to certain strains of Escherichia coli, Proteus vulgaris, and Aerobacter aerogenes, as well as Salmonella pneumonia due to Friedlander's bacillus, and Hemophilus influenzae infections and tularemia.

Streptomycin is administered in much the same fashion as penicillin. However, it is more likely to produce toxic symptoms than is penicillin. In larger doses it sometimes affects the eighth nerve, producing deafness or dizziness or both, which, though usually temporary if the drug is withdrawn, may become permanent. Urticaria is not uncommon as a side effect.

The new antibiotic can be given orally, intramuscularly, intravenously or intrathecally. The intramuscular route is preferable, with 1,000,000 to 3,000,000 units being given daily. Recently the metric system has been adopted in defining dosage, 1 mg. of streptomycin being equal to about 1,000 units. Solutions containing 0.1 to 0.2 gram (100,000 to 200,000 units) per c.c. may be used intramuscularly, but for intravenous administration the twenty-four hour dosage of 1,000,000 to 3,000,000 units should be diluted in 1 or 2 liters of isotonic salt solution. Single injections of as much as 0.1 gram (100,000 units) have been given intrathecally in 5 to 10 c.c. of normal saline. Concentrations of the drug as high as 50,000 units in 1 c.c. of isotonic saline solution have been used for insufflation by a nebulizer for bronchiectasis, without evidence of irritation.

The routine use of streptomycin for urinary tract infection has been disappointing, according to Nichols and Herrell.[2] When the urinary infection was due to Proteus ammoniae or Aerobacter aerogenes, the best results were obtained. It seems important that the urine be alkaline and that urinary stasis be overcome before favorable results can be expected.

If treated early in the disease, tularemia seems to respond well to streptomycin.[1] Influenzal meningitis is another infection which responds well to this new antibiotic. Experience with its use in tuberculosis is thus far insufficient to establish its value in this disease.

A point that deserves consideration is that streptomycin should be given in effective dosage from the start, for it has been found that some strains of bacteria develop resistance to the drug.

Experience with this new antibiotic has been sufficient to prove it a valuable addition to the relatively short list of specific drugs we possess.

FLUIDS IN HEART DISEASE

"SALT-FREE" diets and restriction of fluids in the presence of edema have been in vogue for a number of years. Only recently has it been learned that it is the sodium, whether it be in sodium chloride or sodium bicarbonate, which should be restricted in the presence of edema, from whatever cause, and that limitation of fluids is wrong.

According to theory, the normal interchange of fluid between the circulation and the body tissues depends on hydrostatic pressure and osmosis. With the pressure in the precapillary vessels greater than the osmotic pressure in them, fluid escapes into the tissues. Since pressure in the postcapillary vessels is less than that in the precapillary vessels and is also less than the osmotic pressure in the postcapillary vessels, there is a withdrawal of fluids from the tissues. A lowering of the plasma contents of the blood would result, according to this theory, in a greater diapedesis of fluid from the precapillary vessels into the tissue spaces, and would also cause a lessened absorption of fluid from these spaces into the postcapillary vessels, as a result of the lessened osmotic pressure-effect of the plasma.

In the presence of cardiac decompensation, with diminished cardiac output and increased venous pressure in the postcapillary vessels as well as in the rest of the venous system, the return of fluid to the postcapillary vessels from edematous tissue spaces is hindered. Edema fluid contains salt, among other elements, corresponding to the blood content. Along with venous congestion, then, the kidney output is diminished in quantity, and its sodium chloride content is lowered.

Theoretically then, the reduction of edema should be favored by any factor which improves circulation and relieves venous congestion, by the restriction of salt in the diet and thus in the circulation, and by diuresis, whether it be from increased water intake and elimination through the kidneys or from the administration of mercurial diuretics. This has been found to be the case.

While the value of salt restriction in the presence of edema has been recognized for some years, Schemm was the first to call attention to the fact that if sodium, in the form of sodium chloride and sodium bicarbonate, is eliminated as far as possible from the diet, fluids not only need not be restricted but are beneficial in reducing edema if given in large amounts. While a "salt free" diet is unpleasant for the cardiac patient, the recognition by the physician of the needlessness of thirst in the treatment will be most welcome by the cardiac patient.

MORE NURSES NEEDED

THERE is still a great need for more nurses, both trained nurses and practical nurses. In publicizing the need and the advantages of training in the profession of nursing, a publicity campaign has been undertaken, and informative material has been sent to the Federated Women's Clubs throughout the state and to the members of the Hospital Auxiliary. The subject is one of timely importance and might well be taken up by the Woman's Auxiliary of the Minnesota State Medical Association.

Representatives of the state nursing, hospital and medical associations have been meeting to formulate a bill agreeable to all three interested professions, providing for legislative action for the licensing of practical nurses by the the present legislature. It is to be hoped that agreement as to details will be reached, so that provision will be made for this licensing of practical nurses, a procedure which should stimulate recruiting of young women for the short course in training.

At the special meeting of the House of Delegates of the Minnesota State Medical Association on December 22, 1946, in Saint Paul, approval was given for the establishment of ten more schools of nursing with a three-year course leading to the title of registered nurse, and for twenty additional schools providing one-year courses for the training of practical nurses.

It seems that action will be taken by the present legislature providing for "licensed practical nurses." In anticipation of this outcome and in view of the great need of registered nurses and practical nurses, physicians can render a service by referring young women to the headquarters of the Minnesota Nurses' Association, 2642 University Avenue, Saint Paul 4; to the Franklin Hospital School for Practical Nursing, 501 West Franklin Avenue, Minneapolis 5; or to the Vocational Hospital, 5511 Lyndale Avenue South, Minneapolis 9, for detailed information as to requirements and opportunities for training in nursing.

CONSUMERS COOPERATIVE MEDICAL CARE

THERE is every evidence that Consumers Cooperatives are going to submit legislation to the present legislature to enable them to provide medical service for their members. They propose to furnish this service through the employment of physicians to care for co-operative members and their families. Such services are to be consumer controlled, in contrast to the various plans being promulgated by the various medical associations, and medical care is to be sold like other commodities such as food and merchandise.

One fundamental difference between the Consumers Cooperative plan and types of sickness insurance, a vital difference in the minds of the public as well as the medical profession, is that in co-operative supplied medical care there is no free choice of physician. The co-operative member receives his medical care from the employed physician or surgeon whether he be good, bad or indifferent. If there is one prerogative of which the American citizen is jealous, it is that when he is ill he can obtain what in his mind is the best available medical advice. Physicians, too, have insisted on the importance of maintaining the free choice of physician whenever possible, in order not to abrogate the stimulating effect of free competition on the quality of medical care.

Assuming that co-operatives may be able to employ first-class physicians, it seems quite probable that such physicians, being employes, will of necessity be dictated to in the matter of what services they may give their patients in the way of hospital care, medicines and the like. The holders of the purse strings must of necessity be largely interested in costs, and freedom of medical care is sure to be hampered.

MOBILE SPEECH CLINIC UNDERTAKES SURVEY

A concerted effort is under way to ferret out the speech and hearing handicaps among Minnesota's school-age children—handicaps which may hold them back in their classwork or contribute to making them social behavior problems.

A complete survey of the speech and hearing needs of 400,000 school children is the goal of the Mobile Speech Clinic of the University of Minnesota, staffed by the University and financed by tthe Minnesota Association for Crippled Children and Disabled Adults, Inc., from funds derived through sale of Easter Seals.

Directed by Miss Laila L. Larsen of the University, manned by Miss Larsen and two experienced clinicians and equipped with two pure tone audiometers and a Sound Scriber, the station-wagon-clinic will tour the state for three to five years on a project which both university and Minnesota Association officials hope will do much to waken the general public to the needs of the mentally competent but physically handicapped.

They see the whole problem as a continuous one, not one which can be solved by a traveling clinic in three or four or five years.

They foresee the time when, partly as a result of this initial project, public opinion will support long-range plans to give every child, no matter how remote his home or school, the opportunity to receive expert examination and early treatment of his handicap.

They hope to see the time when more and more special teachers and clinicians will be trained to staff permanent clinics set up to serve given areas of the state.

For purposes of research, the clinic, under the general administration of Dr. Bryng Bryngelson of the University, will gather data regarding such important questions as the effects of foreign language background on speech.

It will attempt to correlate the speech and hearing difficulties of children with behavior problems and with failures in school, especially in spelling and reading.

Still another aim is to compare the effectiveness of testing with pure tone audiometers with that of screening with group test audiometers.

Although the Minnesota survey is not the first of its kind in the United States—others are in progress in Indiana, Iowa, Illinois, Oregon, Pennsylvania, Michigan and California—it is the first ever to use the pure tone machine which tests in all ranges of sound rather than in the speech range only. Every child is examined individually.

Since the staff of three—Miss Larsen, Gertrude Russell, hearing clinician, and Virginia Worthington, speech clinician—set out in their station wagon last September, they have covered two counties, surveyed sixty-seven schools, given 20,398 survey tests.

Through January 20, they had examined 10,866 school children in Washington and Stearns Counties, and had found that one of every five or six had some speech defect, while one of every fourteen or fifteen had a hearing handicap in need of special attention.

Of 9,208 children tested for speech, 614 had marked and 1,034 had slight defects. Of 11,190 tested for hearing, 519 had marked and 261 had slight disabilities.

Every disability, however minor, discovered in the screening test is followed up with a private conference with the child and his parents or teacher. While the first test requires about two minutes, an interview may last from fifteen minutes to an hour while the clinician investigates the background of the handicap.

Individual reports are forwarded to parents and teachers, summary reports and recommendations to the State Board of Education and the clinic's sponsor, the Minnesota Association for Crippled Children.

The clinic concentrates on diagnosis, not prescription, and parents are informed that the individual reports should be passed on to the family doctor to whom the child is taken for treatment.

However, when the clinicians' tests indicate that a child may respond to certain treatment, a recommendation to that effect is enclosed with the routine report.

Results in other states reveal that 20 to 40 per cent of handicaps uncovered in surveys actually do receive follow-up medical care.

Greater co-operation between parents and doctors can raise this percentage, Miss Larsen believes, but frequently the doctor must go out of his way to make up for parents' lack of initiative in bringing their children for treatment.

Often, she believes, the doctor takes it for granted that parents of course will return to him if an infected ear for which he has prescribed does not improve; or if a child, brought for consultation because he has not learned to talk at a normal age, does not overcome his retardedness in a reasonable length of time.

And too often, she continues, parents assume that because the doctor did not specifically request to see the

AMA HOUSE OF DELEGATES AGENDA INDICATE ASSOCIATION'S GROWTH

Several topics were under discussion at the midwinter session of the House of Delegates of the American Medical Association, held in Chicago, December 9 to 11—topics which give evidence of the amazing rapidity with which the association has grown and the multiplicity of its functions.

On the agenda were such important subjects as improving health conditions in the coal mining areas, the possible significance of the new United Mine Workers' Health Fund, and ways and means whereby the medical profession can help the nation successfully realize the maximum benefits from the broad features of the Hill-Burton Hospital Construction Program.

Other matters taken up were the establishment of representation for the Veterans Administration in the fellowship of the association and in the House of Delegates; continued progress in the development of prepayment medical care plans; membership for general practitioners on hospital staffs; certain revisions in the constitution and by-laws; and plans for the observance of the association's one hundredth birthday at the 1947 annual meeting in Atlantic City.

Delegates Meet in "Free Atmosphere"

In a brief address before the assembly, the president, Dr. Harrison H. Shoulders, declared that this meeting "was being held in a different atmosphere from that which existed in July and from that which has been in existence for quite some time." He told the delegates that today's atmosphere "approaches freedom—the freedom to go forward in the accomplishment of the great mission of medicine."

Dr. Shoulders said that the AMA is a strong organization—an organization with a past of which it can be justly proud and a future of which it can be hopeful.

Dr. Olin West, president-elect, added a firm second to Dr. Shoulders' remarks and voiced his confidence in the continued progress of the association in its efforts to promote the art and science of medicine. He called on physicians to do their utmost toward what he termed "the development of new financial techniques which will make medical care more available—the financing of it at least—to people of moderate means."

Conditions in Mining Areas Discussed

Much interest and attention at the conference centered on medical care and sanitary conditions among mine workers and their families. Present to report was Rear Admiral J. T. Boone of the U. S. Navy Medical Corps, who, as medical advisor to the Federal Coal Mines Administrator, organized and has been directing a survey of medical, hospital and general health facilities and sanitary conditions in the areas where bituminous coal is mind.

As a preface to his report of the situation in mining communities, Admiral Boone noted that the war years have been accompanied by "changes and dangers of a legislative nature" and that the medical profession has been confronted with a welter of new laws, bills and regulations bearing directly on public health and medical and hospital care. He reasoned that such proposals as have received so much public support stem from *real* as well as imagined needs of the people. They are symptoms, he said, of dissatisfaction with the medical profession as it practices its art today; and he declared that "physicians themselves should be the first to recognize these symptoms, diagnose the cause and prescribe the remedies, which will not merely allay the complaint, but produce the cure."

Mine Workers' Plight Is Vital Problem

While Admiral Boone recognized the fact that substandard health and sanitary conditions among coal miners is only *one* of the problems facing the medical profession, he said that it was nonetheless of vital importance.

Admiral Boone went on to describe the survey of mining communities which, under his direction, is now rapidly drawing to a close. The survey, initiated some six months ago by the Federal government and the miners' union when the government was operating the mines, Admiral Boone said, called for a review of conditions which would serve as a basis for providing miners some day with medical, housing and sanitary facilities conforming to recognized American standards.

Since the survey report was not yet complete, Admiral Boone did not feel he could reveal any specific and official results or conclusions to the delegates. However, he did present some personal observations, and he called to the attention of the House of Delegates, as a representative group of American doctors, what he said "would seem to be of major concern to organized medicine."

"The apparent weakness in public health programs in the nation's coal mining regions are deeply disturbing," Admiral Boone pointed out. He had observed, as a general rule, such inadequacies as poor water supply controls, improper sewage and garbage disposal, lack of "reasonable safeguards" against contamination from human and animal wastes, lack of protection in food and milk handling, and poor insect and rodent control. The number of mining communities with adequate facilities, he added, were too few in number to stand out as exceptions to this rule.

Lack of Public Health Work

It had been very disappointing, Admiral Boone said, to note what he called "a schism between curative medicine and preventive medicine." To explain this point, he said that, in the communities he visited, he inquired into the public health work done by "company physicians," and he found that very little was done beyond the usual school health programs of immunization. He found physicians so busy with their practice of curative medicine that they were reluctant to concern themselves with assuming leadership in public health, especially when there was so little to work with in the way of understanding and willingness to understand on the part of the miners themselves.

Admiral Boone said he believes that not only does this condition exist in coal mining communities but it exists "far too generally." "I believe," he said, "that organized medicine can perform a noble task in closing the gap between curative medicine and preventive medicine." And he added, "Public health is not exclusively the concern of government."

"What we have seen," said Admiral Boone, referring to the subhealth standards uncovered by his investigations, "should rightly be the concern of every doctor, from the specialist in Chicago and New York to the general practitioner in the Appalachians. The health problem in the coal fields cannot be dismissed as a matter affecting less than 2 per cent of the population of the country or merely a few hundred physicians.

"As you well know, since diseases can become epidemics . . . since illness and disease in one segment of the population can and does affect the health and welfare of the entire nation, I am sure that you agree with me when I say that if we can help raise the health standards of coal-mining communities, we can contribute to the national well-being."

Background of United Mine Workers' Health Fund

Admiral Boone then turned to a discussion of the background and probable implications of the recent establishment by agreement between Secretary of the Interior J. A. Krug and the United Mine Workers' head, John L. Lewis, of the UMW Health Fund, which has been "highly disturbing" to physicians who practice in the coal-mining communities and to other physicians as well.

This fund, which is to be administered by trustees appointed by the president of the UMW, is to be accumulated from wage deductions of mine workers and is to be used for medical, hospital and related purposes "at the discretion of the trustees of the fund."

Collections for the fund, according to Admiral Boone, have not yet started, but what changes in the present system of medical practice will follow its establishment, no one, except possibly a few persons inside the UMW, can foretell.

Said Admiral Boone: "The mine physicians, I understand, are not so much concerned about their economic security as they are about the maintenance of their professional status. That is the concern of all medical men, because the establishment of this particular medical fund may be the precedent for similar funds in other industries."

What changes this new departure, which may inject third parties between physicians and patients, will tend to bring about in medical practice, no one knows, said Admiral Boone. It is evident, however, he added, that the AMA has been handed a problem which cannot and is not overlooking.

"The views which organized medicine takes in handling such problems will help to fashion the pattern that is eventually evolved," Admiral Boone concluded. "Organized medicine must dissipate any emotionalism that beclouds sound reasoning and must assume leadership in the formulation and establishment of reasonable and practical programs that will benefit the people."

Delegates Act on Admiral's Advice

After hearing the Boone report, the Council on Medical Service made definite recommendations with regard to action which the AMA should take. In its report to the House of Delegates, the Reference Committee on Medical Service approved of the action suggested by the council, that the council shall continue to follow closely the developments of the bituminous coal situation. The report said that "it is recognized in these proposals (the UMW Health Fund) a new type of economic philosophy, one with far-reaching implications and concerns, which well may influence and possibly change the whole basic pattern of medical practice.

"The manner in which these funds ultimately will be administered, and the instrumentalities through which medical care will be delivered, will require our careful study and guidance. Such plans as these doubtless will occupy a prominent place in any collective bargaining of the future. . . . We shall have to project ourselves into this developing situation and play a leading role in the evolution of these plans for medical care."

Need for "Planned Co-operation" in Hill-Burton Program Stressed

How the Council on Medical Service is trying to impress all state medical societies with the importance of planned co-operation to the successful carrying out of the provisions of the Hill-Burton law, was reported to the delegates by that body. As a service to state societies it is preparing a set of principles as a guide to such co-operation, and a set of minimum standards for diagnostic clinic facilities.

In addition, the medical profession, through its state and county societies, is being encouraged by the council to participate actively in all plans or programs formulated under the bill. Each state medical society, the council recommends, should have good representation in the agency charged with the responsibility of carrying out the provisions of the law in its particular state.

The council's report to the delegates drew attention to the fact that it is up to the state medical societies to see that facilities are placed only where a specific need for them is shown, and that diagnostic clinic facilities are erected only with the sanction of the county medical society concerned.

Formation of Health Councils Recommended

Among the other recommendations of the Council on Medical Service was one regarding the establishment of a National Health Congress, proposed in January of last year. The report favored "formation of state or local health councils to meet local needs and enlist the co-operation of their interested bodies," and said that the council will continue to work on such a program by calling a meeting of local health councils and other interested groups to discuss the value and scope of such councils and to draw up a model outline for their formation.

The council reported that after much study it feels that the setting up of a National Health Congress as a permanent body would not be advisable. Such a body, it pointed out, "would be bound to duplicate the efforts, and to a certain extent usurp the prerogatives, of this House of Delegates and other AMA bodies."

"In the opinion of the Council," the recommendation read, "it would be far better for the Board of Trustees, the Council on Medical Service and other AMA Councils to call conferences, whenever deemed advisable, on subjects on which the advice and co-operation of their bodies is desirable. In this way, different groups could be called on in matters pertaining to their specific fields; and there would not be one set group to consider every subject." Therefore, the council asked specifically to have its previous instruction for the establishment of a National Health Congress rescinded.

Delegates Act on Variety of Questions

Several important decisions were made by the House of Delegates, specifically:

1. An admendment to the by-laws was voted, making it possible for general officers and delegates in the association to be nominated to the presidency without first having to resign from the position held.

2. The delegates passed an amendment permitting admission to fellowship in the AMA, without payment of dues, to members of the permanent corps of the Veterans Administration, for so long a time as they should remain with the Administration.

3. A resolution turned over to the Board of Trustees for "serious consideration" was one intended to promote closer co-operation between the medical and dental professions by the appointment of a committee of five AMA members to work with a similar committee set up by the American Dental Association, "inasmuch as physicians and dentists have a common interest in the extension of health service." It was recommended that this move be carried through on the state level also.

4. Another resolution called for the establishment of general practice sections in approved hospitals, specifying that these appointments should be made by hospital authorities "on the merits and training of the physician," and that "membership on a hospital staff should not be dependent on certification by the various specialty boards or membership in special sections."

5. The establishment of a certifying board to determine the qualifications for general practice was the subject of a related resolution, asking that the Section on the General Practice of Medicine of the AMA give consideration to a plan for the establishment of such a board, and that the section make a preliminary report to the House of Delegates in June at Atlantic City.

6. As a result of deliberations at this session of the House, there is now at association headquarters a Division of Public Relations, under an executive assistant to the general manager, which will handle public relations activities for all councils, bureaus, publications and other agencies and operations of the association.

7. The delegates approved a resolution directing the Council on Medical Service and the Council on Industrial Health to "continue close co-operation with mine physicians in an effort to improve and maintain the high standards of medical practice."

Bureau of Medical Economics Reorganizes

It was announced by the Bureau of Economic Research (formerly the Bureau of Medical Economics) that under the leadership of its new director, Professor Frank G. Dickinson, it plans to reactivate and expand, with the emphasis on research.

A current job of this bureau is an extensive survey of medical services in each state. Questionnaires are being sent to county medical society secretaries, asking them to draw on a state highway map a line around the area served by physicians located in each county medical center.

The bureau is also assisting with the tabulating and analyzing of the completed questionnaires now pouring in from the thousands of returned medical officers. Reporting that the response in this survey has been remarkable, the bureau promises to study the some 20,000 questionnaires and will file a report with the Committee on National Emergency Medical Service, which is directing the survey, some time in April.

Elaborate Plans for Centennial Announced

Elaborate plans for the AMA centennial celebration in Atlantic City, June 9 to 13, which promises, according to the skeleton outline presented to the delegates, to be "the high point in the assemblages of physicians anywhere in the world," were announced. Plans include a banquet honoring leaders in industry and the various occupations associated with medicine, at which time distinguished speakers will comment on the influence of American medicine on the nation's progress.

A religious service on Sunday, June 8, presenting three great religious leaders who are to speak on the spiritual aspects of medicine and health, will be broadcast from Atlantic City. Plans are to invite ministers throughout the nation to join the observance by speaking on similar topics.

The outline promises that the annual meeting will present the largest technical and scientific exhibit ever developed by the AMA, and will include a public exhibit set up on the boardwalk, depicting the progress of scientific medicine. Genneral and special sessions are scheduled; distinguished foreign guests are being invited, and a motion picture program is planned which will include, among other special showings, a film on the evolution of the scientific medical motion picture.

Washington's "New Political Flavor" Reviewed

Delegates heard a review of the complexion of the new Congress in a report from the Bureau of Legal Medicine and Legislation, in which the names of new committee chairmen were listed and predictions were made as to what the "new political flavor" in Washington would mean in the way of medical legislation.

Plans were announced at the session for a Second Annual National Conference on Rural Health to be held February 7-8 in Chicago, in order to provide farmer and doctor with another opportunity to exchange views regarding the many questions which are of vital importance in developing better health service in rural areas.

The Council on Industrial Health reported that it is watching closely developments in the World Health Organization, noting in its report that "information is not yet available, particularly regarding the status of industrial hygiene in the proposed organization." It was observed that there will probably be a mixed committee of public health experts, representatives of the International Labour Office and the World Health Organization itself, to consider matters of social insurance and industrial hygine. Meanwhile, the council reported, the United Nations organization is establishing itself in New York and is setting up a health program for its employes, who will probably number about 2,000.

Included in the industrial health report was an interesting bit relative to this "Atomic Age." The council is deeply interested in the organization of the Board of Consultants on Atomic Energy, being set up under the sponsorship of the Council on Physical Medicine. The report says that "since it is proposed to use nuclear energy in industry as a source of power, the question of occupational risk is of considerable importance." A symposium of atomic energy in industry and medicine, under the joint auspices of the Council on Physical Medicine and the Council on Industrial Health, was an event of the recently held Seventh Annual Congress on Industrial Health.

Minneapolis Woman Sentenced to Three-year Term for Criminal Abortion

Re. State of Minnesota vs. Clara Olga Anderson, Irene E. McFarland and Isadore Abramovich.

On December 28, 1946, the Hon. Levi M. Hall, Judge of the District Court of Hennepin County, sentenced Clara Olga Anderson, forty-eight years of age, 1142 Emerson Avenue North, Minneapolis, to a term of three years at hard labor in the Woman's Reformatory at Shakopee. The defendant, Anderson, had pleaded guilty on that date to an information charging her with the crime of abortion, and also with having had a previous conviction for a similar offense in 1943. A plea by the defendant's attorney for a suspension of sentence and an opportunity for the defendant to leave the State, was denied by Judge Hall. On the same date Irene E. McFarland, forty-six years of age, 1514 Sixth Street North, Minneapolis, and Isadore Abramovich, twenty-four years of age, 706 Elwood Avenue North, Minneapolis, entered pleas of guilty to an information charging them with the crime of abortion in the same case with the defendant, Anderson. Judge Hall sentenced the defendant, McFarland, to a term of one year in the Minneapolis Woman's Detention Home, suspended the sentence and placed the defendant on probation. The defendant, Abramovich, was sentenced to a one-year term in the Minneapolis Workhouse, the sentence being suspended and the defendant placed on probation.

The three defendants were arrested on December 12, 1946, by Minneapolis police officers, following the admission of a twenty-three-year-old young woman to Minneapolis General Hospital suffering from the aftereffects of a criminal abortion. The investigation disclosed that the defendant, Anderson, attempted to abort the patient by means of a catheter, on December 10, 1946, at the home of the defendant, McFarland. The patient paid the defendant, Anderson, $150 for the criminal abortion of which sum $25.00 was given to the defendant, McFarland, for the use of her home while the abortion was being done. The defendant, Abramovich, employed as a "bouncer" at a Minneapolis bar, was arrested when it was disclosed that he was the contact man for the criminal abortion.

The defendant, Anderson, has a previous conviction for criminal abortion, having pleaded guilty in the District Court of Hennepin County, on March 25, 1943, to an indictment charging her with the crime of abortion. In that case Mrs. Anderson was sentenced to a term of not to exceed four years at Shakopee, but was placed on probation after serving one year in the Minneapolis Woman's Detention Home. None of the defendants has a license to practice any form of healing in the State of Minnesota.

POSTOPERATIVE ANURIA

Complicated by Duodenal Ulcer, Hemorrhage, Bilateral Pneumonia and Toxic Urticaria

L. A. STELTER, M.D.,
Minneapolis, Minnesota

The term oliguria, meaning deficient secretion of urine, and the word anuria, meaning scanty urine, may be used interchangeably, as they represent symptoms of some critical urinary disease. They represent the failure of the kidneys to excrete urine, and the longer the condition exists the more rapidly the state of uremia is approached.

The term uremia, introduced by Piory in 1848 to denote a state of intoxication due to resorption of urine, has now come to include all the toxic states which develop as a result of renal insufficiency. Uremia may be acute or chronic, the acute type arising from rapid suppression of urine; and the chronic type occuring from diseases which cause a slowly developing state of intoxication.

In 1821, Prevost and Dumas discovered that urea accumulated in the blood of a dog following removal of both kidneys. Bright, in 1836, knew that people suffering from nephritis had an increase in blood urea. According to Musser, severe intoxication may be manifest from 60 to 100 mg. per cent of urea; while in more chronic processes, where there is a gradual accumulation, mild symptoms may appear only after values higher than 100 mg. per cent. Values have been observed as high as 1,000 mg. per cent.

Creatinine values, normally 1 to 3 mg. per cent, may rise as high as 60 mg. per cent, but values above 5 mg. may have a serious prognosis, suggesting a fatal outcome. Recoveries have been recorded when creatinine has risen as high as 12 mg. per cent.

Rehberg and Holten calculated that 100 to 150 c.c. of fluid must filter through the glomeruli of the kidney per minute to accomplish the usual excretion of creatinine. Calculations were based on investigations of Vimtrup that the human kidney contains 2,000,000 glomeruli with a total surface of approximately 1.6 square meters. The effective pressure for filtration through the glomerular membrane is the difference between the glomeruli blood pressure and the force opposed by the osmotic pressure within the Bowman's capsule. If the number of glomeruli are reduced by disease, the filtration must necessarily be reduced. Similarly, fluctuations in the plasma protein have a direct effect upon the degree of filtration which is decreased if the protein content is increased.

Causes of Oliguria and Anuria

The causes of oliguria and anuria are numerous, and the most important may be listed as follows:

1. Kidney diseases in the terminal state; nephritis and nephrosis.
2. Toxic manifestations due to poisons, drugs, intravenous fluids or medications, and eclampsia.
3. Mechanical obstruction due to calculi, bilateral tumors including the ureters, surgical ligation of the ureters. Papin cited five cases of carcinoma of the rectum with anuria as the initial symptom. Nephroptosis has also been given as a mechanical cause.
4. Hysteria. Gordon reported a case of an hysterical woman with anuria which lasted two days and was cured by suggestion. Grenier saw an hysterical woman through five attacks of anuria lasting two, four, six, seven and fifteen days, respectively.
5. Surgical anuria resulting from shock, sympathetic trauma, and anuria from unknown cause following surgery.

Little has been written about this unfortunate disaster following a surgical procedure on the urinary tract or following a general surgical operation. Most authors stress the catastrophe as being due to varying blood pressure levels during an operative procedure or the result of blood transfusions (incompatible blood) in combating shock, where the blood pressure is definitely lowered and where a surgical procedure had been of long duration accompanied by fluctuating blood pressure.

Coller found that continuous inhalant anesthesia over long periods of time may affect the output of urine, but he was unable to find any evidence of either ether or cyclopropane causing any gross effect on glomeruli permeability.

Sturmia states that when incompatible blood is injected intravenously, rapid hemolysis occurs with the clinical symptoms of a chill, nausea, vomiting, lumbar pain, tightness and constriction of the chest, and elevated temperature following almost at once. There may be additional symptoms of abdominal pain, bladder pain and the urge to defecate. Transient hemoglobinuria with scant reddish brown urine appears, followed in a few hours by jaundice. The jaundice reaches its peak in twenty-four hours. The oliguria may improve and the patient may recover rapidly but more often it leads to uremia and death.

Sturmia lists as possible causes of oliguria (1) blockage of the renal tubules, (2) anaphylaxis, (3) ischemia of the kidneys from vasomotor constriction, and (4) nephrotoxic substances released by hemolysis. The first three he refutes but believes the fourth more feasible as there is a strong similarity pathologically between post-transfusion nephrosis and chemical nephropathies.

Dr. Stelter appeared on the program by invitation.

Bywaters showed in crushed muscle necrosis, causing shock, in the early blitz of London, that patients seemed to do well for several days, only to develop elevated blood pressure and die as a result of suppressed renal function. Two-thirds of the patients died at the end of the first week, the majority on the sixth day. About one-third of the cases recovered because urinary output was maintained.

Treatment

The treatment is chiefly preventive. Proper blood grouping and cross-matching are necessary before transfusions are given. It is well to establish alkaline diuresis by large doses of sodium bicarbonate by mouth until the urine is alkaline. The alkalinity should be maintained. If the patient is vomiting, a fresh solution of 1.4 per cent sodium bicarbonate may be given intravenously. Isotonic sodium lactate may be given intravenously. Fluid intake should be kept up to 2 to 3 liters a day, with sufficient saline to keep up the chloride level. If renal failure occurs, the treatment is identical; the addition of mercurial diuretics may be introduced, and decapsulation of the kidney considered.

Case Report

G. L., No. 1327311, aged thirty-six, white, an engineer by occupation, entered Fairview hospital at 2:00 P.M. on February 28, 1945, complaining of pain in the right lower abdomen and flank. He had become acutely ill at 2:00 A.M. and ascribed his illness to a few highballs and a heavy meal at a banquet the night before. During the night the pain became more intense, radiating down the right side and towards the back. There was nausea but no vomiting. He had no urinary disturbance, no nocturia, and no testicular pain, but felt some discomfort in the scrotum.

His past health had been good except for some indigestion; he had intolerance to fried and fatty foods and rare meats. Cabbage and oranges always gave him distress. For the past year or two, he had had some pain in the right side. Six months prior to the present illness he had a similar attack, at which time he went to another clinic where gastrointestinal, gall-bladder and colon studies revealed nothing abnormal. He was advised to have his appendix removed on the basis of a probable retrocecal location. This he refused to have done and returned to his home and work.

Physical examination revealed a robust, well-developed male, acutely ill. Except for the abdomen, physical examination revealed nothing abnormal. His pulse was 76, temperature 99.4° F.; blood pressure was 124 systolic and 75 diastolic, in millimeters of mercury. The contour of the abdomen was normal. The muscles were spastic. Palpation revealed no tumor nor masses, but the muscles of the right side were held rigid and he complained of tenderness in the right lower quadrant. There was also tenderness in the right lumbar region on Murphy percussion. There was no rebound tenderness and the testicles were not sensitive. The extremities and reflexes were normal. Rectal examination revealed nothing of note. A tentative diagnosis of acute appendicitis or some right-sided nephritic disease, ureteral stone or perinephritis, was made.

Laboratory tests showed a hemoglobin of 91 per cent. There were 11,900 white blood cells in each cubic millimeter of blood. Differential examination showed segmented neutrophiles 82 per cent, lymphocytes 16 per cent, monocytes 2 per cent. Urinalysis was normal except for two red cells and three pus cells in the high dry field. Specific gravity of the urine was 1.022. A scout film of the abdomen revealed nothing abnormal.

In spite of the above findings, I decided against surgical intervention, and on March 1, 1945, rechecked the laboratory procedures and found the urine normal except for four pus cells in a high dry field. The leukocyte and differential counts were normal. On March 2, 1945, an intravenous pyelogram revealed a marked hydronephrosis of the right kidney. The condition was discussed with the patient and he was advised to have a cystoscopic examination and a retrograde pyelogram made. He elected to have this done at a future date and returned to his home.

On March 7, 1945, he returned to Fairview hospital, and repeat laboratory examinations were within normal limits. On March 8, a cystoscopic examination was performed by Dr. R. T. Soderlind, who noted that "prostate, bladder and meatus were normal. Indocarmine appeared in normal time from the left meatus. No dye appeared from the right meatus although urine was spurting. A catheter was passed to the right pelvis and 50 c.c. of urine aspirated. A No. 6 catheter was left indwelling. A pyelogram revealed marked hydonephrosis of the right kidney."

Operation was advised and the patient was prepared for operation. His blood was grouped, matched and cross-matched for blood transfusions; fluids were forced, and sulfadiazine and sodium bicarbonate given. On March 11, an indwelling catheter was passed into the right ureter to reduce the size of the hydronephrosis. Urine from the right ureter showed three pus cells in a high dry field. No tubercle bacilli were found. The blood urea was 13 mg. per cent, creatinine 1.2 mg. per cent.

On March 14, 1945, the right kidney was removed under cyclopropane anesthesia. Operating time was one hour thirty-four minutes. Extensive adhesions and induration around the entire capsule made the procedure more difficult. The patient received 5 per cent glucose in normal saline intravenously during the operation. His pulse varied between 90 and 130 per minute, and his blood pressure from 100 systolic, 70 diastolic, to 154 systolic and 90 diastolic, in millimeters of mercury. He returned to his room in good condition.

Five hundred cubic centimeters of normal saline and 500 c.c. of citrated blood were given intravenously in the afternoon following the operation. He made satisfactory progress, and the blood pressure and pulse were normal. At 9:30 that night he was catheterized and 400 c.c. of urine obtained. At midnight he tolerated 1,000 c.c. of 5 per cent glucose in distilled water, and had a fair night. At 6:00 A.M., March 15, he complained of severe chest pain, generalized distress, dyspnea, and a faint feeling. His pulse became thready, weak and rapid; the rate rose to 150 per minute. The blood pressure was 80 systolic and the diastolic could not be heard. He was given neosynephrin, 250 c.c. of plasma intravenously, 500 c.c. of normal saline, and 500 c.c. of citrated blood, after which he rallied from shock and his blood pressure rose to 110 systolic and 70 diastolic, and his pulse stabilized at about 110. At 9:30 A.M., March 15, he was catheterized and 5 c.c. of urine obtained. In the afternoon the patient became confused and irrational, but this was only transitory. An indwelling catheter was inserted in the bladder and 5 c.c. of urine obtained. Penicillin, 20,000 units, was given every three hours. One thousand cubic centimeters of 5 per cent glucose in normal saline and 1,000 cubic centimeters of 5 per cent glucose in distilled water were given intravenously morning and afternoon. Copious fluids were given by mouth, with large doses of alkalies, in an effort to establish diuresis. On March 16, nasal suction was instituted because of abdominal distension. On March 17, the condition of the patient was unchanged. The wound was inspected and the drains removed. In spite of the large fluid intake and the elevated metabolites, the condition of the patient remained fairly good. He showed no gross evidence of uremia. His skin, however, became deeply bronzed and jaundiced, reaching its height on the fourth day. On March 18, Dr. Soderlind passed a catheter into the left ureter and also left a Foley catheter in the bladder. Supportive treatment and forced fluid intake were continued. When the nasal suction could be clamped off, alkalies were given in large amounts. In the evening the patient began to doze a great deal; in waking intervals he became very restless and irritable. His blood pressure rose gradually up to 180 systolic and 78 diastolic. His pulse slowed.

On March 19, Dr. Theodore Sweetser saw the patient in consultation and recommended increase in fluid intake, hot packs and diathermy over the left kidney. Decapsulation was suggested if the urine did not increase in amount. On March 20, at about 8:30 A.M., he became very restless and irritable. He was put in restraints, and he thrashed about. At 8:45 he had a convulsion of several minutes' duration, which, according to the nurse, occurred after he lapsed into deep coma. Dr. Sweetser advised decapsulation of the left kidney under local and gas anesthesia.

The capsule of the left kidney was stripped completely, anteriorly and posteriorly, the poles explored and found normal, and the wound closed rapidly. He stood this operation surprisingly well. In his room, saline and another transfusion were started. At 4:30 P.M., the ureteral catheter began to drip and by 7:45, about 50 c.c. of urine had been collected. At 11:45 P.M., 100 c.c. more had been excreted. However, the patient's condition was critical and he was placed under an oxygen tent, which he constantly attempted to tear off. His twitching and muscular jerkings were controlled by sodium luminal.

His general condition from now on showed a gradual improvement, though he remained unconscious. The right wound was torn open by positioning on the operating table. By March 23, he was removed from the oxygen tent. On March 25, he developed a very harsh cough, elevated temperature and expectoration. X-rays of his chest revealed nothing noteworthy. His cough subsided and he again seemed to improve.

On March 27, following a hard coughing spell, during which time he raised a great deal of thick purulent mucus, he had a defecation of black stool, found to be blood. On account of repeated positive findings of blood in the stool, a diagnosis was made of bleeding duodenal ulcer and he was treated by the Cook County bleeding ulcer regime. He was kept on the diet, given creamalin, vitamin K, thiamin chloride, vitamin C, liver extract, and repeated blood transfusions, to which he responded well.

He continued to improve, and on April 24, the wound of the right side was completely debrided and closed with interrupted silk sutures. It now healed readily, and on May 1 he was allowed to sit up. At 11:30 A.M. on May 2 the patient developed dyspnea and pain in his left chest. His symptoms simulated those of a pulmonary embolism and for a while it was feared he would expire. X-rays on May 6, following a similar attack in the right chest, revealed pneumonia on both sides. He again responded to penicillin and an oxygen tent, and roentgenograms on May 9 showed the pneumonia to be subsiding on the left side. On May 13, when he seemed well on his way to recovery, giant urticaria developed over his entire body. Penicillin was discontinued and the urticaria responded to epinephrine. On May 15, the patient was allowed out of bed while all attendants held their breath for fear of another catastrophe. On May 19, he left the hospital in ambulatory condition.

The surgical specimen showed a large kidney with multiple abscesses, massive suppuration and liquefaction. The infection was nontubercular. The diagnosis was multiple carbuncles of the kidney.

Stomach x-ray studies on July 7, 1945, by Dr. J. Kelby, verified the diagnosis of duodenal ulcer.

The patient's health to date has been good. A recent examination revealed normal blood and urinary findings, and his last weight was 197 pounds.

Comment

It is my opinion that this patient had a postoperative anuria resulting from a transfusion reaction, the reaction occurring about fourteen hours after the transfusion. This delay I cannot explain. Ordinary routine care, based on the treatment of uremia, failed to alter the picture. Uremic convulsions ensued and, as a last resort, decapsulation was done. It is possible that splitting the capsule and manipulating the kidney decompressed the glomeruli sufficiently to permit the excretion of urine. A biopsy of the kidney would have given valuable information. The numerous complications of wound disruption, bilateral pneumonia, bleeding duodenal ulcer, and urticaria were coincidental to the illness, and only added to the patient's discomfort and the attendants' grief.

Discussion

DR. CLARENCE DENNIS: I have nothing to contribute, but I would like to ask a question for my own information. There is evidence to believe that alkalinzing urine does not have any benefit in preventing renal damage. I am curious.

DR. L. A. STELTER: Alkalinization has been suggested in the literature to help prevent reactions in blood transfusions.

DR. EDMUND FLINK: There are a few comments which I would like to make regarding the problem of reaction of the urine in relation to renal damage from hemoglobinuria. I carried out some experiments, causing hemoglobin solution in dogs which had a strongly acid urine and in dogs which had alkaline urine, and obtained renal biopsy thereafter. Renal damage with uremia resulted whether the urine was acid or alkaline. The number of dogs was not great. At the time when the urine was strongly alkaline as well as when the urine was acid, hemoglobin precipitated in the tubules, toxic changes occurred, and one couldn't distinguish the kidneys of the dogs that had acid and alkaline urine. The dogs which developed renal damage had the highest plasma hemoglobin levels, regardless of urine reaction. No renal damage developed when relatively lower hemoglobin levels were found.

One bit of evidence is presented in black water fever which results in anuria in quite a number of cases. The mortality rate in a large series of patients whose urine was alkalinized as soon as hemoglobin appeared in the urine is the same as in an even longer series of patients to whom alkalies were not given.

There has been recent work which would support the idea that alkalinization has benefit. Yulie has clamped both renal arteries in rabbits for fifteen to twenty minutes and injected small amounts of hemoglobin solution. The animals that had alkaline urine suffered no kidney damage at all, and those that had acid urine had severe kidney damage, similar to transfusion reaction kidneys. His idea was based on the fact that transfusion reaction is often accompanied by shock-like state, renal anoxia, et cetera, and he was trying to simulate that condition. Thus, there may be some evidence that alkalinization is of use. The original basis of alkalinization was on rather flimsy ground. The work of Baker and Dodds, who used very few rabbits for their experiments, gives very little pertinent data and their conclusions are not convincing. DeGowin, who carried out a large number of experiments on dogs, still left the question open. I don't know what the answer is. If one is going to accomplish anything, however, alkalinization before transfusion, or at least immediately after demonstrating a hemolytic reaction, should be carried out promptly. One must be certain the urine becomes alkaline too. A great deal of harm can result from the indiscriminate administration of a large volume of alkali to a patient with anuria or oliguria. I am quite certain that attempts to alkalinize the urine once anuria has developed will not be of the slightest value and may be harmful.

There are several other ideas. Those patients received sulfadiazine at the time of anuria. Sulfadiazine possibly contributed to kidney damage. Another thing, whenever one has a transfusion reaction, it is well to find out immediately whether or not there is a hemolytic reaction. One easy way is to obtain a specimen of plasma or serum immediately. If the serum or plasma is obtained carefully, there will be no hemoglobin visible normally, but if there has been a hemolytic reaction, there will always be hemoglobin present in sufficient quantity to color the plasma red. Normal appearing plasma or serum will ease one's mind that a febrile reaction is not a hemolytic reaction. On the other hand, absolutely essential information will be obtained when a true hemolytic reaction has occurred.

THE USE OF CHEMICAL AGENTS IN THE TREATMENT OF HYPERTHYROIDISM

EDMUND B. FLINK, M.D.
Minneapolis, Minnesota

In May of 1943, E. B. Astwood of Boston[1] published a report on the reduction of basal metabolic rate and the abolition of signs and symptoms of hyperthyroidism in three patients using thiourea and thiouracil by mouth.

In 1941, MacKenzie, MacKenzie and McCollum[12] reported a remarkable enlargement of the thyroid in animals which had been fed sulfaguanidine. Two simultaneously published studies by MacKenzie and MacKenzie[11] and Astwood, Sullivan, Bissell and Tyslowitz[4] made clear the unique nature of the new goitrogenic agents of which sulfaguanidine is the prototype and thiouracil the best known example.

The goiters produced by these agents, unlike those produced by the older goitrogens,[10,15,17] viz. soy beans, thiocyanate, cabbage and seeds of the Brassica family, generally cannot be prevented or abolished by iodine administration. The currently accepted view[3,11,14] of the action of thiouracil, as characteristic of the new thyroid drugs, is that it inhibits the uptake of iodine and the formation of thyroid hormone by the thyroid gland,[3,8,14,16] colloid typically being reduced or depleted,[4,11] and basal metabolic rate falling. In the presence of normal thyroid function, the pituitary is believed to overact, producing hyperemia and epithelial hyperplasia of the thyroid; this explanation of the thyroid hyperplasia is based upon (1) the known action of the thyrotropic hormone of the pituitary, (2) observable histologic changes in the pituitary following sulfaguanidine administration, (3) the ability of administered thyroxin to prevent or abolish thiouracil-induced hyperplasia of the thyroid, (4) the absence of thyroid hyperplasia in hypophysectomized animals given the new goitrogens.[4,11]

Thiouracil (2-thiouracil)[2] was found to be the most potent of the earlier substances tested. More recently, ethyl and N-propylthiouracil have been found to be more active than thiouracil. Thiourea, thiobarbital, and various substituted ureas are active agents also.

More than 5,000 patients have been treated with thiouracil since 1943. We have had experience treating approximately sixty-five patients with thiouracil at the University Hospital. Most of the patients were treated as a preoperative measure. Six patients, however, were maintained for long periods on thiouracil. Two patients have been lost from sight since discontinuing the drug. One adolescent girl has been able to stop the medication without recurrence of symptoms. Two adults have repeatedly demonstrated that there is prompt return of symptoms after discontinuing thiouracil, even eighteen or more months from the time of starting therapy.

The speed of response as measured by the basal metabolic rate, by weight gain, et cetera, has compared favorably to that obtained by other investigators. The basal metabolic rate dropped to +20 per cent in from four to eight weeks. Patients who had iodine before starting thiouracil responded more slowly than those who had not had iodine previously. Most of the patients had moderately severe to severe hyperthyroidism.

Failure to control symptoms adequately has occurred in three cases even after continued administration for as long as three months. Perhaps longer trial would have been successful, but thyroidectomy was carried out in each instance, successfully in two but resulting in death shortly after operation in one. All had had iodine for varying periods before thiouracil therapy, with very poor results and obviously were resistant to further action of iodine. They had large nodular goiters, had basal metabolic rates over +50 per cent, and had at least some cardiac disability. Two were diabetics.

When the patients were in an approximately normal state of metabolism, thyroidectomy was usually carried out without event. In several instances thyroidectomy presented some technical difficulties. When the basal metabolic rate was normal before operation, the postoperative convalescence was as uneventful as after operations on a nontoxic goiter. The routine use of iodine for several weeks before contemplated operation has decreased the technical difficulties appreciably.

The largest single group of patients treated for a prolonged time is that of Williams.[20] One hundred patients were followed for a period of many months. Forty-nine patients have had remissions lasting from three to twenty-one months, and fifty-one have had relapses in from two weeks to five months (most of them in one month). X-ray therapy, coincident thyroid administration, type of hyperthyroidism and severity of the hyperthyroidism had no significant effect on the percentage of relapses. Males tended to have many more relapses than females (fifteen out of nineteen males). Patients with large glands tended to relapse more frequently than others.

The most important consideration of all is the frequency and severity of toxic reactions. The largest collected series analyzed the records of 5,745 treated patients.[18] Thirteen per cent had some toxic reactions. Granulocytopenia occurred in 2.5 per cent of cases, and 80 per cent of these occurred by the twelfth week. A mortality rate of 0.4 per cent has been reported and all deaths have been attributed to agranulocytosis. There is no evidence that folic acid, pyridoxine or any vitamin influences the course or prevents the complication. By controlling infection, penicillin appears to be the best therapeutic agent for agranulocytosis. Other important toxic reactions include fever, rash, arthralgia, delirium, purpura, salivary gland enlargement, neuritis, headache, and jaundice. Reports of smaller series of cases have indicated an incidence of 10 to 16 per cent toxicity.[13]

The recommended dose is from 0.4 to 0.6 gm. per day in divided doses until the basal metabolic rate approaches normal, after which the dose can be reduced to 0.1 to 0.4 gm per day. It is well to administer iodine in full doses for ten to fourteen days before contemplated surgery. If iodine has been administered within a month, it is not advisable to stop iodine during the course of treatment.

Because of serious toxic reactions, thiouracil probably should be used only in patients who have one of the following conditions: (1) thyrotoxic heart disease with or without auricular fibrillation, (2) organic heart disease complicated by coincident hyperthyroidism, (3) severe hyperthyroidism treated with iodine for a variable period without adequate response, and (4) patients refusing surgery or other treatment. Careful follow-up must be possible. Leukocyte counts three times a week, frequent check for fever, skin rashes, other symptoms, and observations of the bleeding mechanism must be made. After several months vigilance can be relaxed somewhat but leukocyte counts should be determined every week then.

Danowski, Man and Winkler[7] have recommended the use of small doses of thiourea along with iodine as a form of maintenance therapy in hyperthyroidism. They have treated fifty-four cases successfully. Two patients developed fever shortly after starting thiourea. The dose used ranged from 0.07 gm. to 0.28 gm. of thiourea and 15 drops of strong solution of iodine a day. The response was more prompt in almost every case than in the usual experience with thiourea or thiouracil alone.

N-propyl thiouracil is a recent addition to the group of goitrogenic drugs. In animals it is effective in 1/6 to 1/10 of the dose of thiouracil. Astwood[5] reported the treatment of thirty-five patients without any toxic effects. Now over 600 cases have been treated but there are instances of drug fever, leukopenia, skin rashes and other similar complications. Doctors Bieter and Troxil of the Department of Pharmacology have been supervising its use here at the University of Minnesota. Fifteen cases have been treated. Two patients developed fever and leukopenia (and one a severe rash also). Propyl thiouracil may not have been the cause in either case. One patient developed a severe rash and fever from phenobarbital. Satisfactory response has occurred in eleven cases, no response in one case and toxic reactions in two cases. The period of observation was too short in one. The responses have been comparable to the ones observed when thiouracil is administered. Propyl thiouracil has been administered in doses of 75 mg. per day, but more recently up to 200 mg. have been recommended. It appears to have definite advantages over thiouracil but still is not without dangerous toxic complications.

The use of radiation therapy in hyperthyroidism is well known. It is effective in a fairly high percentage of cases. The idea of the use of "internal radiation," using various radioactive isotopes of iodine, has been current for about ten years, but the unavailability of radioactive iodine and various other factors have limited its application.

Hertz and Roberts[9] reported the results of treatment of twenty-nine patients with radioactive iodine, and Chapman and Evans[6] reported the treatment of twenty-two additional patients. Both groups used I^{130} (with a small amount of I^{131}). I^{130} has a half life of twelve hours, and I^{131} has a half life of eight days. Both substances emit beta rays in the process of decomposition. The calculation of dose of isotope used depended on the following data: (1) fractional uptake of radioactive iodine by the thyroid, (2) the known energy of the radiations from I^{130} and $I,^{131}$ (3) the clinical estimation of the weight of the thyroid of the patient, and (4) the known pattern of uptake and retention of radioactive iodine by hyperplastic thyroid gland of hyperthyroidism.

Hertz and Roberts[9] used from 1.5 to 28 m.c. of I^{130} giving an estimated 500 to 2,500 roentgens (plus or minus 50 per cent) to the thyroid. Of twenty-eight patients whom they felt had received adequate dosage (questioned by Evans and Chapman[6], five patients underwent subtotal thyroidectomy partly as a means to evaluate therapy. Twenty patients are not thyrotoxic, and three patients must be considered failures, three or more years after therapy. Every patient who had a subtotal thyroidectomy developed myxedema or hypometabolism, indicating continued progress of involution after the thyroidectomy.

Chapman and Evans[6] used much larger doses—from 0.5 to 1.2 m.c. per gm. of estimated thyroid weight. In a series of twenty-two patients so treated, twenty are either nontoxic or myxedematous, and only two failed to show a return to normal metabolic state. The decline in basal metabolic rate to normal occurred over an average period of sixty days. Five patients had multiple doses. It is apparent that this last series of cases from the Massachusetts General Hospital responded more promptly and completely than those of Hertz and Roberts.

In order to carry out such therapy adequately, it is imperative that a competent physicist be able to follow the treatment, measuring carefully the amount excreted, the calculation of dose, et cetera.

One patient has been treated with I^{131} (half-life of eight days) at the University Hospital. Doctor Stenstrom and the staff of his laboratory have carried out the necessary calculations of dosage, excretion, and uptake by the gland, in terms of roentgen equivalents. The patient is a twenty-nine-year-old woman with very severe hyperthyroidism of about six months' duration.

Her basal metabolic rate at time of hospital admission, after taking iodine for three weeks, was +65 per cent. Her condition has been precarious. Propyl thiouracil was started, but a generalized skin eruption, leukopenia and fever developed shortly afterward. This actually proved to be due to phenobarbital rather than propyl thiouracil. Too short a time has elapsed since giving the radio-iodine to determine what the response will be, but she has improved quite definitely now.

Conclusions

The mode of action, effectiveness, dangers and indications of the thiouracil group of drugs have been reviewed. These agents have added a great deal to our understanding of the physiology of the thyroid gland and have proved to be of very real value in the control of hyperthyroidism. The thiouracil compounds do not supplant thyroidectomy, but merely supplement it at the present time.

Radioactive iodine gives promise of being an important tool in the medical therapy of hyperthyroidism. Since its use depends on fairly elaborate equipment and a thorough knowledge of physics, for the present only a few clinics and hospitals are able to use radioactive materials.

EXTERIORIZATION PROCEDURES FOR COLON INJURIES

U. SCHUYLER ANDERSON, M.D.

Minneapolis, Minnesota

In addition to well-established principles which are followed in the management of intra-abdominal trauma, exteriorization procedures for large bowel injuries have been found extremely valuable. For the purpose of discussion, exteriorization procedures may be considered to include not only the actual exteriorization of the damaged segment of bowel but also colostomies formed proximal to the site of injury in a part of bowel which cannot be brought outside the abdominal cavity. However, it is important to note the distinction between exteriorization of a wounded segment of bowel and the construction of a colostomy for the purpose of defunctionalizing the distal segment. At times both purposes may be accomplished by one and the same procedure, but a clear understanding of the purpose of the operation is necessary to the selection of the techniques involved.

While stationed at army general hospitals, one in this country, and one overseas, the author became impressed with the usefulness of exteriorization, when about fifty patients with colostomies which had been made in the treatment of battle injuries of the colon and rectum at overseas army medical installations came under his care. The management of these colostomy patients and a partial review of the literature constitute the basis of this paper. The author has had no experience with the initial treatment of battle injuries in the forward areas. It is, therefore, with understanding and realization of the difficulties encountered by surgeons in the front line regions, and the knowledge that hindsight is easier than foresight, that certain critical observations are made.

The wisdom of exteriorization of wounds of the colon was emphasized repeatedly during the late war. Ogilvie,[9] in reviewing the results of surgery in the western desert, contended that the principle of exclusion of all damaged parts of the large intestine until repair is complete, applies to all injuries, even suspected ones, and to all parts of the bowel, particularly the extraperitoneal portion of the rectum. From directives and bulletins issued by the Surgeon General's Office, in which broad policies and guiding principles on the care of the wounded were presented, it can be learned that exteriorization of the injured bowel was considered the established procedure. Proximal colosotomy was regarded as mandatory in the treatment of wounds of the rectum. Primary closure of wounds of the unprepared colon, as found in battle casualties, was deemed unwise and unsafe.

Ogilvie[9] cited a case which is illustrative. Primary suture of a retroperitoneal tear of the descending colon, with drainage of the retroperitoneal region, was accomplished. Later a fecal fistula developed, and the patient died on the ninth day. Autopsy showed the wound of the colon to be broken down over a large area. Fecal matter lay free in the retroperitoneal tissues, and a severe general peritonitis was present. Comment by the surgeon was: "Suture alone seemed adequate; a proximal colostomy should have been made."

The following case, which was among those observed by the author, also serves to illustrate the probable unwise choice of primary suture of a perforated colon rather than exteriorization.

The patient incurred a gunshot wound of the abdomen with the point of entrance in the right lumbar region and the point of exit in the left lower quadrant of the abdomen. At laparatomy ten hours after injury, a perforation 3 centimeters in diameter was found in the upper portion of the sigmoid colon. The perforation was closed. On arrival at an overseas general hospital, a fecal fistula was present in the lower left quadrant of the abdomen. The external opening of the fistula was the original wound of exit. At this hospital a loop colostomy of the transverse colon was made and multiple bone fragments were removed from the left ilium. After admission to a general hospital in this country, it was found that the patient had the following conditions: a fecal fistula, a poorly functioning loop colostomy of the transverse colon, compound comminuted fractures of the left ilium and sacrum with osteomyelitis of these bones, an atonic bladder, anal sphincter incompetence and partial paralysis of the left lower extremity. It was determined by x-ray examination, after lipiodal injection, that the fistula communicated with the upper sigmoid colon. Since the loop colostomy did not completely divert the fecal stream and therefore did not defunctionalize the distal bowel, revision of the transverse colostomy with separation of the stomata was done. Later, the perforated portion of the sigmoid colon and the fecal fistula were excised, and end-to-end anastomosis accomplished. The chronic osteomyelitis required drainage and sequestrectomy. The transverse colostomy was permitted to remain because of the incompetent anal sphincters. It is believed that exteriorization of the perforated portion of the sigmoid colon and the formation of a double-barrel colostomy at the time of the first laparotomy would have been the better procedure for this patient. Exteriorization would have prevented the formation of the fecal fistula and might well have lessened the severity of the osteomyelitis.

In reviewing the literature, it was found that authors who had had first-hand experience with battle injuries were almost without exception in favor of some type of exteriorization of all battle injuries of the colon. Horsley[6] stated that there is no dispute concerning exteriorization of the wounded bowel. Mason[8] followed the dictum, "exteriorize all colon injuries." Such strict adherence to the principle of exterioration of all colon injuries may be debatable in civilian-type injuries. Hoffert reported at this society two cases of civilian-type injury to the colon in which exteriorization was employed with successful results in both cases.

Although there appears to be little or no argument concerning the value of exteriorization of battle injuries of the colon, there is considerable controversy over the methods of accomplishing the exteriorization, such as the technique involved and the type of colostomy to be employed. It is believed by some surgeons that the simple tube or loop colostomy, when properly performed, will completely shunt the fecal stream and defunctionalize the distal segment, while it is considered by others that the loop colostomy is inefficient and that complete defunctionalization of the distal bowel can only be obtained by forming a colostomy with separated stomata. It is felt by the latter that fecal material is bound to get into the distal bowel if the colostomy is covered by the same dressing. In observing the colostomies of those patients which came under the author's management, it did not seem that there was always a clear understanding of the purpose of the operation at the time the colostomy was made. This was particularly true of proximal colostomies whose apparent intended purpose was to defunctionalize the distal bowel but, because of the technique used, could at best only decompress the bowel. Many of these patients arrived at the general hospital with the distal colon and rectum filled with feces. This was especially troublesome in those patients suffering from wounds of the buttocks and perineum which communicated with the rectum and which frequently were associated with compound fractures of the pelvic bones.

In order that a better understanding of the purpose of the operation can be acquired, Mason[8] has grouped trauma of the colon as follows: (1) perforations of the antemesenteric portion up to one-half the diameter of segment; (2) perforations of the mesenteric and antemesenteric border larger than one-half of the diameter; (3) severely torn segments necessitating resection of a segment; (4) complete transections; (5) injuries to the mesentery producing nonviable segments; (6) the first five groups occurring in the rectosigmoid above the pelvic floor; (7) the same five groups occurring between the pelvic peritoneum and anus; and (8) injuries necessitating right colectomy or cecectomy. Using a classification of this type, the exteriorization of the bowel should be planned and the colostomy constructed, bearing in mind not only the simplest and easiest closure later but, what is more important, the real purpose of the exteriorization.

Ordinarily two types of colostomies are employed: (1) the tangential, simple, no-spur loop or tube colostomy and (2) the long, double-barrel colostomy with or without separation of the stomach. According to Mason,[8] injuries of the colon fall in groups as stated above; and Groups 1, 6, and 7 should be treated by the simple, no-spur, loop colostomy. There is no question concerning the Group 1 injuries, since a loop colostomy will handle adequately the small antemesenteric or lateral perforations and lacerations. One questions that a loop colostomy, no matter how performed, will completely defunctionalize the lower bowel and rectum in Groups 6 and 7 injuries. It is believed that the time would be well spent, providing the patient's condition permits, in constructing a colostomy which will completely defunctionalize the lower segment. This can only be accomplished by the formation of a colostomy with separated stomata, whether this be the Devine type or a no-spur colostomy with separated stomata necessitating end-to-end closure later. The usual double-barrel colostomy with approximated stomata will permit feces to gravitate from the proximal stoma to the distal stoma. Exclusion-type colostomies should be constructed, particularly for large intraperitoneal perforations or lacerations of rectum, where it is obvious a long time will elapse before healing and where secondary closure of the rectal wound will be necessary. Extensive damage to lower bowel segments, associated injury of bladder and urethra, and rectal injuries with compound fractures of the pelvis are examples of injuries which require a prolonged and complete defunctioning artificial anus. Under these circumstances, the exteriorized loops should be made sufficiently long to allow for complete transverse section and some separation of the stomata. As ultimate closure will be by end-to-end suture, the formation of a spur is undesirable. The formation of a skin bridge between the arms of the loops might, in fact, be preferable.

The loop colostomy may be used for small perforations of the rectosigmoid, suspected perforations of the rectum, or when the patient's condition is such that the additional time required to construct a completely diverting type would greatly add to the risk of the operation. However, certain details in the formation of the loop colostomy, as recommended by Horsley,[6] Mason[8] and Fallis,[3] should be observed. For exteriorizations or loop colostomies in the lower quadrants of the abdomen, short, laterally placed incisions which follow the direction of the fibres of the external oblique, similar to the McBurney incision, should be used. For colostomy of the transverse colon, a transverse incision through either rectus muscle, as advocated by Fallis,[3] is indicated. The transverse incision will obviate the necessity of rotating the loops or twisting the bowel in its axis to permit delivery. Adequate mobilization without tension is extremely important in preventing retraction. It should be recalled that about one-half the diameter of the right colon, both flexures, and a portion of the rectosigmoid lie retroperitoneally, and that the lateral mesenteric attachments are for the most part avascular. Lateral incisions in the mesocolon can be made with impunity in procuring mobilization. Even with adequate mobilization there is a tendency for loop colostomies to retract. For this reason, a glass rod or rubber tube should be placed under the loop to be maintained in place for several weeks if necessary. Retraction causes the colostomy to degenerate into a useless fistula, which may be difficult to repair or may lead to intraperitoneal sepsis or abdominal wall abscess. The loop colostomy should be opened as soon as it is made, in the long axis of the antemesenteric border of the bowel, not necessarily in a longitudinal band. About two-thirds of the incision should be over the proximal loop and one-third toward the distal loop. The mesenteric border of the bowel will be undisturbed and will rest against the glass rod or tube. Often this type of colostomy can simply be closed by suturing the longitudinal incision transversely. The closed loop can then be placed extraperitoneally or intraperitoneally as seems most desirable.

Injuries of the colon falling in Groups 2, 3, 4 and 5 of Mason's[8] classification should be treated by the construction of a double-barrel spur colostomy, according to Mason. This type of colostomy and exteriorization would permit extraperitoneal closure after crushing the spur. It was Mason's belief that exteriorization of these injuries without formation of a spur would result in a complicated procedure in re-establishment of the continuity of the bowel. This is contrary to the opinions of Keene[7] and Hamilton and Cattanach,[4] who prefer excision of the colostomy and end-to-end intraperitoneal closure as a one-stage procedure rather than the spur-crushing, extraperitoneal two-stage procedure. The author has, on several occasions, closed colostomies intraperitoneally with excellent results and no untoward effects. As has been emphasized by Coller and Vaughn,[3] Pemberton and Black,[10] the peritoneal cavity will stand the contamination of intraperitoneal closure of a colostomy or open end-to-end anastomosis better than the abdominal wall tissues at the site of the colostomy.

Injuries of the ascending colon and cecum are extremely difficult to manage. Various exteriorizations procedures have been recommended. Tangential perforation of the cecum may be treated by tube cecostomy but preferably by exteriorization. Cecostomy, even when necessary because of direct injury, should never be used as a substitute for a proximal colostomy when indications are present for the latter. Extensive injuries necessitating resection of the cecum and ascending colon were treated by a number of different methods. In one method, after resection, a terminal ileostomy was created in a separate incision in the right lower quadrant, and the distal end of the colon was exteriorized below the costal margin. Occasionally an ileocolostomy was done and the distal end of the colon exteriorized as a colostomy. The formation of a double-barrel colostomy, one limb of which is the distal colon and the other limb the terminal ileum, has been suggested as another way of handling these injuries.[1] Such a combined proximated ileostomy and colostomy could be closed extraperitoneally after crushing the spur.

It would seem a simple matter to close a colostomy. However, the fairly large number of papers written on the closure of colostomies by authors with large experience attests to the fact that difficulties are encountered. It was the author's experience to find that a large number of colostomies were attended with complications or problems such as retractions, herniation of the bowel subcutaneously, interposed foreign bowel or mesentery between the colostomy loops, varying degrees of rotation of one limb of the colostomy around the other limb, secondary perforations or fistulae adjacent to the colostomy, and inflammatory or granulomatous masses involving the colostomy. These complications prohibited or precluded the use of the Paul-Miculicz technique or spur-crushing extraperitoneal closure. Excision of the colostomy, followed by intraperitoneal, open or closed, end-to-end anastomosis, was accomplished in these cases, with excellent results. Where a well-defined spur is present, the usual spur-crushing extraperitoneal closure can be used. Whatever method of closure is used, the contamination of the abdominal wall tissues should be handled either by delayed closure, as used by Coller and Vaughn[3] and Pemberton and Black,[10] or by subcutaneous drainage.

Summary

The value of exteriorization procedures for colon injuries is emphasized.

The techniques involved and the indications for the various methods of exteriorization are discussed.

When the intended purpose of the exteriorization procedure is defunctionalization of the distal bowel it is believed that a formal type of colostomy with separated stomata should be made, rather than a simple loop colostomy.

Discussion

Dr. Robert J. Tenner: Dr. Anderson has presented a very interesting and excellent discussion of the problem of colostomy and exteriorization procedures for colon injuries.

I would like to emphasize the importance of an exclusion type of colostomy. My experience in an Army General Hospital was very similar to Dr. Anderson's, and I saw several cases of chronic fecal fistulas which I believe would have been prevented if the colostomies which were established had completely diverted the fecal stream.

When it is deemed advisable to make a colostomy, whether for decompression in the case of an obstructing carcinomatous lesion or for protection of the sutured colon after repair of an injury, I feel the fecal stream should be diverted completely. I have seen colostomies which only partially diverted the fecal current, and I believe these were so constructed, in part at least, to facilitate the later closure of the bowel in a retroperitoneal or so-called aseptic manner. This aid to later closure of the stoma is no longer necessary, in my opinion, in that with the aid of chemotherapy plus the immunity present in these cases there is little or no risk or danger to the procedure of colostomy closure. At our hospital we closed over fifty colostomies. These closure cases were prepared for five days preoperatively with 15 to 20 gm. of sulfasuccidine daily, and then the stoma was closed and the wound sutured in layers. In some instances an extraperitoneal closure was done, but more often the colon was put back into the peritoneal cavity, free on its mesentery. All cases healed well and with no further difficulty. Therefore, I feel it is important to establish a completely exclusion type of colostomy in order to accomplish the main purpose at hand, in those cases where for any reason a colostomy is indicated.

There is a point I would like to mention in connection with the construction of a transverse colostomy when such a procedure is indicated. I feel it is advisable to make use of the protective properties of the omentum in these cases. An opening should be made in the omentum distal to its attachment to the transverse colon and by reaching through this opening, a loop of the colon can be delivered which will be surrounded by a collar of omentum. After the colon has been exteriorized and the wound closed, the omentum is in direct contact with the peritoneum of the anterior abdominal wall and thus seals off the peritoneal cavity from contamination and protects against possible herniation of the small intestine through the wound. Also when the colonic stoma is later closed, the omentum affords excellent protection against possible leakage which might occur at the suture line.

Dr. Hamlin Mattson: Colon injuries constituted 22 per cent of all intra-abdominal visceral injuries in World War I. At Wakeman Hospital Center, most of our colon surgery consisted in closing colostomies made overseas. We saw loop colostomies. I do not recall seeing one with separated stomata. We did end-to-end sutures and dropped the colon back into the peritoneal cavity. By this method better repair of the fascial hiatus is possible. The peritoneum is much better able to cope with infection than is the abdominal wall. The abdominal wall was drained. With chemotherapy and suction tubes in the lower small bowel, we are permitted greater boldness in colon surgery than heretofore.

We saw posterior colonic fistulas from bullet wounds through the ascending and sometimes descending colon where no mesentery is present. In the former it seemed best to do right hemicolectomy, while in fistulas from the descending colon the preferable procedure seemed to be repair of the colon after rotation, followed by a temporary transverse colostomy, Devine type.

Dr. Nathan C. Plimpton: I was very much interested in Dr. Anderson's paper and the comments. These men were at one end of the line while I was at the other. We often wondered what happened to the men we operated on, and my only follow-ups were a few scattered letters from some of my patients.

It is evident from what was presented here tonight that some colon injuries would have been better treated by an exclusion type of colostomy. In the European Theater of Operations, by directive, we did loop colostomies, and I think it is a good operation for most of the cases it was done on. Our group was about evenly divided between repairing the injuries to the colon and doing a proximal colostomy, and by exteriorizing the injured segment. I used to prefer the former when possible because I could delay the opening of the colostomy a day or so, thereby saving the wound from some contamination. Also, I preferred bringing my colostomies through a separate wound, usually a transverse incision when a transverse colostomy was done. One trick we employed when there was a single hole in the colon was to exteriorize that particular part of the bowel and repair it, with the hope that it would hold. Of course, it never did, but the wound was spared several days contamination. It was our feeling at the time these colostomies were done that, because the distal loop of the colon was already full of feces, it would not make much difference if there was some drainage from the proximal loop into the distal loop as long as we had performed a decompression.

Another argument for this procedure is that it is quick and simple, which is quite a factor when there is a backlog of ten to fifteen men in the preoperative tent who need abdominal and chest operations. I quite agree that all retroperitoneal wounds of the colon should be drained directly to the outside, in addition to the proximal colostomies. One thing we learned was that in the rather severe wounds of the rectum it is better to do a proximal transverse rather than a sigmoid colostomy, because in the final repair it might be necessary to mobilize enough sigmoid to anastomose it with the lower rectum, and if the latter procedure is done, it would add to the difficulty of the final operation.

Dr. U. S. Anderson: Before this meeting, I tried to find someone who had served in a field or evacuation hospital to tell of his experiences in making these colostomies. I was unable to find anyone, and I am therefore glad that Dr. Plimpton has told us something about his experiences. All of us who were in general hospitals, both in this country and overseas, marveled at the excellent work of the surgeons in the field and evacuation hospitals. I did not wish to give the impression that all of the colostomies were made incorrectly. Many of them were made correctly, subsequently closed and the patients returned to duty. As I stated in my paper, I had had no first-hand experience with battle casualties, but believe I could understand and appreciate the many difficulties under which the surgeons in the forward areas worked.

◆ Reports and Announcements ◆

MEDICAL BROADCAST FOR FEBRUARY

The following radio schedule of talks on medical and dental subjects by William O'Brien, M.D., Director of Postgraduate Medical Education, University of Minnesota, is sponsored by the Minnesota State Medical Association, the Minnesota State Dental Association, the Minnesota Hospital Service Association in co-operation with the Minnesota Hospital Association and the Minnesota Nurses Association, and the University of Minnesota School of the Air.

AMERICAN CONGRESS ON OBSTETRICS AND GYNECOLOGY

The program of the Third American Congress on Obstetrics and Gynecology, to be held September 8-12, 1947, in St. Louis, will feature general sessions for all groups making up the congress as well as smaller individual group meetings and round-table discussions. The morning sessions will be panel-type presentations of the following subjects: September 9, Anesthesia and Analgesia; September 10, Cancer; and September 11, Cesarean Section.

The afternoon meetings of the medical section of the congress will consider on September 9, Psychosomatic Aspects of Pregnancy; on September 10, Pregnancy Complicating Cardiac Disease, Diabetes and Tuberculosis; and on September 11, Recent Advances in Endocrinology.

Round-table discussions from four to five o'clock daily will consider such topics as etiology of abortion, asphyxia, fibroids, prolonged labor, infertility, early ambulation, adolescence, treatment of abortion, genital relaxation, ovulation, the menopause, the cystic ovary, uterine bleeding, nutrition in pregnancy, geriatric gynecology, endometriosis and erythroblastosis.

Concurrent sessions and round tables for nurses, hospital administrators and public health workers are being arranged.

The popular forceps and breech demonstrations, that attracted so much attention at the second congress in 1942, will be increased in number so that eighteen demonstrations per day will be held, six each at nine, one and five o'clock daily.

A large scientific and educational exhibit is being set up under the direction of Dr. J. P. Pratt of Detroit, and a comprehensive motion picture program is being arranged by Dr. John Parks of Washington, D. C. The committees assisting these doctors will review applications by prospective participants late this spring. Anyone wishing to make application for space in the scientific exhibit or for time on the motion picture program may obtain the proper blanks from the office of the congress at 24 West Ohio Street, Chicago 10, Illinois.

SECOND SOUTH AMERICAN CONGRESS OF NEUROSURGERY

The second South American Congress of Neurosurgery will be held in Santiago, Chile, April 21-27, 1947. Subjects which will receive special attention include Hydrocephalus, Histology in Brain Tumors (Gliomas and Paragliomas) in Relation to Clinical Findings, and Brain Abscess.

As the meeting is sponsored by the Chilean government, embassies and consulates of Chile have been instructed to grant free visas to those wishing to attend and to extend maximum facilities for obtaining the necessary travel permits.

The registration fee of $18.00 (United States) includes the cost of a copy of the Proceedings of the Congress.

Copy of the program and further information may be obtained from Dr. Carlos Villavicencio, Instituto de Neurocirugia y Neuropatologia, Casilla 70, Santiago, Chile.

EXAMINATIONS FOR APPOINTMENT TO REGULAR CORPS, USPHS

Competitive written examinations for appointment to the Regular Corps of the USPHS to fill some seventy-five vacancies will be held on April 14 and 15, 1947, at various locations. The oral examinations will be held from February 13 to April 9 in strategically located cities. One of these is Minneapolis and the date set is February 27.

Commissions are available to scientists trained in bacteriology, mycology, parasitology, entomology, biology, chemistry, physiology, physics, psychology, et cetera. Salary for assistant scientists is $3,811, and for senior assistant scientists, $4,351 with allowance for dependents.

Application forms and additional information can be obtained from the Surgeon General, USPHS, Washington 25, D. C.

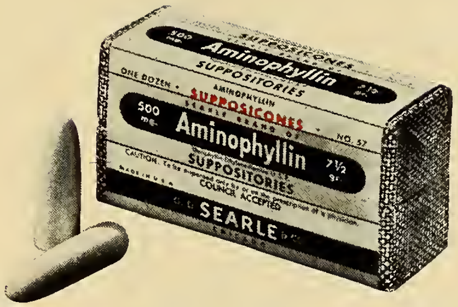
for prolonged optimum effect:



Aminophyllin Supposicones —(SEARLE BRAND OF AMINOPHYLLIN SUPPOSITORIES)

The improved Aminophyllin Supposicone developed by Searle Research provides an excellent vehicle for prolonged and complete absorption of the contained medicament (7½ gr. of Searle Aminophyllin*).

Supposicones are unlike all suppositories known heretofore—the specially prepared base results in prompt disintegration in the rectum at body temperature, yet no refrigerated storage is necessary.

Aminophyllin Supposicones are nonirritating to the rectal mucosa—no anesthetic is required—and they are properly sized and shaped for easy insertion and retention.

ACCEPTED AMERICAN MEDICAL ASSN Council on Pharmacy and Chemistry

In boxes of 12.

**Searle Aminophyllin contains at least 80% of anhydrous theophyllin. Supposicones is the registered trademark of G. D. Searle & Co., Chicago 80, Illinois.*

SEARLE RESEARCH IN THE SERVICE OF MEDICINE

WOMAN'S AUXILIARY

STATE BOARD MEETING

The fall board meeting of the Woman's Auxiliary to the Minnesota State Medical Association was held at the University Club in Saint Paul, Friday, December 6, 1946.

Mrs. Jesse D. Hamer, Phoenix, Arizona, president of the Auxiliary to the American Medical Association, was present and brought a very interesting message to the board members. A luncheon followed the business meeting.

Hennepin County

On December 6, 1946, the Hennepin County Auxiliary held its annual Christmas tea in the Medical Arts lounge. Mrs. Jesse D. Hamer, Phoenix, Arizona, national president, and Mrs. Melvin S. Henderson, Rochester, state president, were guests of honor.

Mrs. Leonard Arling read "The First Christmas Tree," and Mrs. Elmer O. Dahl and Mrs. Arthur A. Wohlrabe were tea hostesses.

A luncheon was given at the Radisson Hotel, January 3, 1947.

Mr. E. C. Peterson of the Baker Peterson Floral Company gave a demonstration of floral arrangements.

Mrs. Gerald M. Koepke made the luncheon arrangements and Mrs. C. A. Boreen was hospitality chairman.

Mower County

The Mower County Auxiliary met Monday, December 30, 1946, at the home of Mrs. J. K. McKenna, with eleven members present.

Mrs. H. B. Allen presided as Mrs. P. C. Leck gave an interesting outline of the Christmas seal work. She traced the progress of the seal from its origin in 1903 in Denmark to its present date. She told how in 1904 the National Tuberculosis Association was organized to study tuberculosis in all its forms, to spread knowledge as to its causes, treatment and prevention.

The Auxiliary voted to purchase a $5.00 tuberculosis bond.

Luncheon followed the meeting.

Red River Valley

The Red River Valley Medical Auxiliary met Tuesday evening, January 7, 1947, at the home of Mrs. O. K. Behr, Crookston. Mrs. M. O. Oppegaard, president, presided at the business meeting which was followed by several tables of bridge.

Mrs. J. P. Anderson of Red Lake Falls was the high-score prize winner. The out-of-town guests were Mrs. W. E. Anderson of Clearbrook and Mrs. C. H. Holmstrom and Mrs. M. J. Bechtel of Warren.

Refreshments were served by Mrs. Behr.

The meeting followed the annual banquet held in the Red and Gold room of Hotel Crookston, attended by members of the Red River Valley Medical Association and the Auxiliary.

Waseca County

Dr. and Mrs. Clifford Wadd of Janesville entertained the members of the Waseca County Medical Society and their wives at a dinner at Hotel Waseca, January 7, 1947.

At the business meeting of the auxiliary, held after the dinner, the following officers were elected: President, Mrs. B. J. Gallagher, Waseca; Vice President, Mrs. Ray Hottinger, Janesville; Secretary-Treasurer, Mrs. R. D. Davis, Clearbrook.

Winona County

Winona County Auxiliary members attended a dinner with their husbands Monday evening, January 6, 1947, at the Winona Hotel, Winona, Minnesota. A business meeting followed the dinner.

REPORTS AND ANNOUNCEMENTS

(Continued from Page 204)

MINNESOTA PATHOLOGICAL SOCIETY

The regular meeting of the Minnesota Pathological Society was held in the Medical Science Amphitheater of the University of Minnesota Medical School on January 21, at 8:00 p.m. The featured address, "Rehabilitation Following Semi-starvation in Man," was given by Dr. Ancel Keys.

UNIVERSITY GRADUATES AVAILABLE FOR ASSISTANTSHIPS

The University of Minnesota Medical School is graduating a senior class on August 29, 1947. Some of these young physicians have expressed an interest to engage in further training on a preceptorship basis or to serve as office assistants for periods of from three to nine months pending the beginning of regular internships.

Any physician in Minnesota or in the midwest who is interested to discuss such an arrangement with students at the University of Minnesota Medical School may correspond with Dr. M. M. Weaver, Assistant Dean and Secretary of the Committee on Internships, University of Minnesota Medical School.

WASHINGTON COUNTY

The Washington County Medical Society was addressed at its January 14, 1947, meeting by Dr. Karl H. Pfuetze, director and superintendent of the Mineral Spring Sanatorium. Chest x-rays of some eighty-eight high school students, teachers and janitors who had had positive Mantoux reactions were interpreted.

Medicine is the only profession that labors incessantly to destroy the reason for its own existence.—Lord Bryce.

In Memoriam

HARRY WINSLOW ALLEN

Dr. H. W. Allen of Minneapolis passed away on December 28, 1946, following a year's illness.

Dr. Allen was born at Bath, Maine, on July 10, 1872. He lived in Red Wing, Minnesota, before attending the University of Minnesota, from which he received B.S. and M.S. degrees in 1895 and his M.D. degree in 1900.

He was a member of the Hennepin County Medical Society, the Minnesota State and American Medical Associations, and a staff member of St. Barnabas Hospital. For many years he was medical examiner for the Claim Department of the Minneapolis and St. Louis Railway.

Dr. Allen is survived by his wife and a sister, Mrs. George Murfin, Lake Minnetonka.

GEORGE RALPH CHRISTIE

Dr. George Ralph Christie, of Long Prairie, died in Asbury Hospital in Minneapolis on January 20, 1947, in his eighty-seventh year.

Dr. Christie had practiced medicine at Long Prairie for sixty years. He was born in 1858 and graduated from the University of Illinois in 1882. Although he retired some years ago, he continued to be prominent in local business and civic affairs and was well known in Minneapolis.

His immediate survivors are three sons; Dr. Robert of Long Prairie, George W., editor of the Red Lake Falls *Gazette;* and Donald R., of Perham.

Funeral services were held on Wednesday, January 22, at 2 p.m. and interment was at Long Prairie.

DONALD MICHAEL DECOURCY

Dr. Donald Michael DeCourcy was born in Saint Paul, on March 3, 1902, and died suddenly on May 28, 1946. He was buried in St. Mary's cemetery, Minneapolis.

He attended St. John's grade school on Dayton's Bluff and later graduated from St. Thomas Military Academy, Saint Paul. While at St. Thomas College, where he took his pre-medical course, he played halfback in football, played hockey, was Minnesota State collegiate singles champion in tennis. In 1919 he won the Colonel Perkins silver tennis trophy and was Saint Paul city tennis champion in 1922 and 1925. He graduated from Marquette Medical School in 1929, and while there he played defense on Marquette's undefeated hockey teams of 1927 and 1928, who were the Northern Collegiate Champions. He earned a place for himself in Marquette's Hockey Hall of Fame.

He interned at St. Joseph's Hospital, Saint Paul, from 1929 to 1930. He maintained an office on Dayton's Bluff since his graduation and was affiliated with the Veterans Hospital, where he served in the capacity of orthopedic surgeon. He was on the staffs of Mounds Park, St. John's and St. Joseph's Hospitals. He was

a member of the Minnesota State and American Medical Associations, and the Ramsey County Medical Society. He was also a member of the Phi Chi medical fraternity.

He is survived by his wife, Elizabeth Talbot DeCourcy, whom he married on June 19, 1937, and two sons, Donald Michael, Jr., and Michael Talbot DeCourcy, who was born about one hour after his father's death.

James Wilson, M.D.

DOMINICK PATRICK DEMPSEY

Dr. Dominick P. Dempsey of Wabasha died November 30, 1946, at the age of seventy-six.

He was born at Clermont, Iowa, on September 9, 1870. After receiving a B.S. degree from Valparaiso University in 1903, he obtained his medical education at Creighton Medical School in Omaha, graduating in 1906. He interned at St. Mary's Hospital in Minneapolis and opened an office in Kellogg, Minnesota, and in Wabasha in conjunction with Drs. Lester and Doherty in 1907.

Dr. Dempsey was a member of the Wabasha County Medical Society, the Minnesota State and American Medical Associations.

He is survived by a sister who lives in Dubuque, Iowa, and several nephews and nieces in Iowa and Nebraska.

JOHN JOSEPH EDERER

Dr. John J. Ederer, formerly of Mahnomen, Minnesota, passed away December 11, 1946, in Minneapolis, following a heart attack, after an illness of almost two years.

He was born at Morton, Minnesota, on March 9, 1905. After attending North Dakota University for two years, he took his medical course at the University of Minnesota, graduating in 1930. His internship was served at the United States Marine Hospital in New York. At one time he practiced in Morris and Bellingham, Minnesota, and was an army physician from 1934 until 1936.

Dr. Ederer owned and operated the Mahnomen Hospital at Mahnomen, Minnesota, for four years before retiring in 1944. He was a member of the Red River Valley Medical Society and served as examining physiciain for the Selective Service for a period of four years in Mahnomen County. He was elected president of the Mahnomen Golf Club in 1939.

Dr. Ederer is survived by his wife, Celeste, and two sons, John H. and Paul F. Ederer.

HENRY B. GRIMES

Dr. H. B. Grimes of Madelia, Minnesota, died July 18, 1946, at the age of sixty-nine.

He was born in Mansfield, Ohio, on September 8, 1877. He received his medical degree from the University of Michigan in 1903 and interned at St. Mary's Hospital in Rochester, Minnesota.

After practicing at Lake Crystal, Minnesota, from 1904 until 1911, he moved to Madelia. In 1918 and 1919 he served as captain in the Medical Corps of the army and later was a major in the army medical reserve.

Dr. Grimes was a member of the Watonwan County Medical Society, the Minnesota State and American Medical Associations, and the Southern Minnesota Medical Association.

ELEANOR JANE HILL

Dr. Eleanor J. Hill of Minneapolis, one of the first women graduates of the University of Minnesota Medical School, died December 12, 1946, at the age of seventy-eight.

Dr. Hill was born at Rockwood, Ontario, August 1, 1868. She received her M.D. degree in 1902 and interned at the State Hospital for the Insane at Jamestown, North Dakota, staying there from 1902 until 1907.

She was head of the prenatal clinic at the Northeast Neighborhood House, school physician for the Minneapolis Board of Education, and was a member of the staff at Asbury and Northwestern Hospitals. She was also a member of the Hennepin County Medical Society, the Minnesota State and American Medical Associations.

Dr. Hill is survived by a sister, Mrs. Abbie A. Pearce of Minneapolis, and two brothers, Charles F. Hill, Ontario, and George A. Hill, Jersey City, New Jersey.

ARNOLD PLANKERS

Dr. Arnold Plankers of Saint Paul died December 26, 1946, at the age of sixty-two.

He attended Central High School and Hamline University, Saint Paul, and the University of Minnesota, where he played football. He received his medical degree from Creighton University in 1910, and a few years later began practice in Saint Paul.

CHARLES E. REMY

Dr. Charles E. Remy, superintendent of the Minneapolis General Hospital from 1930 to 1937, died December 16, 1946, at the Wesley Memorial Hospital in Chicago.

After leaving Minneapolis in 1937, Dr. Remy was associated with the Knickerbocker Hospital in New York.

JESSE LYNN MACBETH

Dr. J. L. Macbeth of St. Clair, Minnesota, died November 19, 1946, at the age of sixty-six, following a lingering illness.

Dr. Macbeth was born in Tivoli township, Minnesota, June 20, 1880.

He received his medical education at Fort Wayne Medical College, graduating in 1905, and began practice in St. Clair in 1906. In 1920 he married Sadie Eaton of Mankato.

Dr. Macbeth was a member of the Blue Earth County Medical Society and the Minnesota State and American Medical Associations.

He is survived by his widow, by three brothers, Walter and George, of Mankato, and Dr. A. H. Macbeth, Fort Wayne, Indiana, and by three sisters, Mrs. Nellie Redner and Mrs. Mary Britt, of North Dakota, and Mrs. Carrie Britt, Eagle Lake.

VICTOR E. VERNE

Dr. Victor E. Verne, brother of the late Dr. Paul C. Verne of Minneapolis, died December 1, 1946.

Dr. V. E. Verne was born in Minneapolis, March 2, 1883. He graduated from the University of Minnesota Medical School and was a member of the Nu Sigma Nu medical fraternity.

He began practice at Parkers Prairie in 1906 and became associated with Dr. O. J. Hagen in Moorhead, Minnesota, in 1910. In 1914 he established his own office. In 1918 he joined the Medical Corps of the army and was later discharged as a captain.

In 1922 Dr. Verne moved to Long Beach, California, where he had since practiced.

Dr. Verne is survived by his wife and two children.

Communication

St. Cloud, Minnesota
November 27, 1946
Re: Our Forgotten Children

Dear Dr. Drake:

I am writing to you, the editor of Minnesota Medicine about a matter which I feel is important. If, when I get through telling you my story, you too feel that it is worthwhile, perhaps you would like to write an article for your Minnesota Medicine regarding it.

Minnesota has many good public, private and parochial schools which take care of the educational needs of most of the children of our state. There is, however, a group of children, which up until now, has received very little attention. I refer to the homebound crippled children of our state. The reason for this neglect, I believe, is not that people have not been interested in them, but rather, because the cases are scattered and people have not known about them. It is therefore up to some of us who do know what the situation is, and what the possibilities are, to do what we can to see that life is made as normal and satisfying as possible for these deserving children. This, among other things, includes the opportunity to get an education.

St. Cloud has been the pioneer in this field of effort, and is the only city in Minnesota which has in operation at the present time Home School for Shut-in Crippled Children, conducted through its public schools. Minneapolis has just recently begun operations to provide Home School for its shut-in crippled children.

As long as 1935, the school authorities of St. Cloud recognized the needs and rights of physically handicapped children of our city and mapped out a program of education for them. The work was first carried out through a WPA project, which was planned and supervised by the public schools, with the actual home school work being carried out by WPA teachers. When WPA was discontinued, interested members of the St. Cloud Public Schools Administration collected information from other states concerning the operation of classes for their physically handicapped children and finally, in 1943, wrote a bill which they presented before the Minnesota State Legislature. It was supported by many interested civic and education groups. The bill was passed and became a law. Ever since that time our home classes for physically handicapped children have operated under the new law, with expenses of operation being born by the state. Though this law has been in operation in Minnesota since 1943, no other school district outside of St. Cloud, and now Minneapolis, has availed itself of its opportunities.

The question is, should there not be many more classes for home-bound physically handicapped children in operation in various public school systems scattered throughout the State of Minnesota, to care for our handicapped children? Included in this group are heart cases, spastic cases, rheumatic fever cases, polio cases, and crippled children. Could not a little teamwork and publicity work on the part of doctors, school superintendents, and our State Department of Education bring education to these deserving children? The machinery to do the job is already set up and ready to go, but it isn't being used. Can't we do our bit to give these deserving youngsters the same break that normal children have? Why add a mental handicap to the physical handicap which they already have to bear?

Would you care, Dr. Drake, to bring this problem to the attention of the doctors of the state, through your MINNESOTA MEDICINE, urging them to call to the attention of their superintendents of schools the physically handicapped children of their town, who are being denied an education, just because they can't go to school and get it? I am also at this time writing to the Editor of our *Minnesota Education Journal*, in an effort to bring this matter to the attention of the superintendents and teachers of our state. They seem not to know that a law has been passed to take care of these children. All we need is a little understanding and teamwork and the job can be done. If the doctors will report the cases to the school superintendents and the school superintendents will write to the State Department of Education for permission to set up Home Teaching, the State of Minnesota has already said it would pay the bill. Simple, isn't it?

Thank you very much for anything you may care to do about the matter.

Sincerely,
MARTHA VAN BRUSSEL,
Grade Supervisor

* * *

EDITOR'S NOTE: The above letter from Miss Van Brussel calls attention to the provision, by the state, for free home instruction of crippled children of school age unable to attend school or the special public school classes. In Minneapolis the Dowling School and in Saint Paul the Lindsay School for crippled children provide special instruction and free transportation for handicapped children who are able to take advantage of these special schools. In the cities and country districts, there are many additional youngsters who are confined to their homes and, therefore, unable to acquire an education. These children are known to physicians.

If physicians would report the names of such children to the Board of Education of the local school district, and the Board in turn would report to the Special Class Section of the State Department of Health the names of five or more children living near enough to each other to make visiting by a teacher practical, something might be accomplished.

In order to qualify for such home instruction, each child must be provided with a certificate from a qualified physician, stating the nature and extent of the disability and that the child is one so "deformed or impaired in body or limb" as to be unable to attend special school classes with other children. As home enrollment has a tendency to increase each year, the state reserves the right to require yearly examination of those enrolled.

St. Cloud was the instigator of this worthy movement, and Minneapolis has just recently taken advantage of the provisions of the 1943 law. The rest of the state might well get in line.

* * *

CORRECTION

Due to a typographical error, the wrong dosage was given in the last line in the case summary of the article on Epilepsy which appeared on Page 50 of the January issue. The line should read: Dilantin sodium, *0.1 gm.* twice daily, was prescribed.

Dr. Hartvig Roholt, son of Dr. and Mrs. Christian L. Roholt, of Waverly, received his medical degree at the mid-year commencement at the University of Minnesota. Dr. Roholt is completing his internship at the Milwaukee County Hospital, Milwaukee, Wisconsin.

* * *

Dr. Haddow M, Keith, of the Mayo Clinic, has been in New York City for a meeting of the American League Against Epilepsy and the Association for Research in Nervous and Mental Disease. Dr. Keith, who has been vice president of the League, was elected president for the current year.

* * *

Dr. Charles E. Turbak has taken over Dr. Charles E. Baker's offices and practice in Herman.

Dr. Baker, who moved to Fergus Falls some months ago, had been holding office hours in Herman several days each week until a permanent medical practitioner could be secured.

* * *

A portrait in oils of the late Dr. Franklin Raiter, of Cloquet, has been hung in the local hospital. The unveiling, which was held on December 24, was witnessed by men, women and children from all walks of life, representative of the patients to whom Dr. Raiter had given a devoted service.

* * *

Dr. Marland R. Williams, Cannon Falls, has been joined in practice by Dr. Harold J. Anderson, formerly of Saint Paul. Dr. Anderson, a graduate of the University of Minnesota Medical School, was recently discharged from military service, where he was a surgeon in the Army Air Corps.

* * *

Dr. William B. Halme is now associated in practice with Drs. Reino H. Puumala and Marie K. Bepko at the new Cloquet Medical Center. Dr. Halme, who is a former resident of the Kettle River-Automba community, was recently appointed a member of the courtesy staff of St. Luke's Hospital, Duluth.

* * *

Dr. Allan E. Moe has completed his three-year fellowship in Internal Medicine at the Mayo Foundation and received an M.S. degree in science from the University of Minnesota at the December commencement. After February 1, 1947, Dr. Moe will be associated with the Fargo Clinic at Fargo, North Dakota.

* * *

Dr. Frank Falsetti, of Rochester, who was recently released from the Army Medical Corps, is taking postgraduate work at the University of Minnesota School of Medicine. At the time of his induction into military service in 1944, Dr. Falsetti had an orthopedic residency at St. Vincent's Hospital in Toledo, Ohio.

DISTRIBUTORS OF

A Complete Line of Drugs for

Every Medical and Hospital Need

In addition to the hospital and medical equipment, instruments and supplies of all kinds, that we handle, we are also distributors for a complete line of pharmaceuticals manufactured by the Ulmer Pharmacal Company. This is an extremely high quality as well as economical line of Ethical Drug Specialties and General Pharmaceuticals, including:

- **OINTMENTS**
- **AMPOULES**
- **TABLETS**
- **CAPSULES**
- **VITAMINS**
- **and many SPECIALTY ITEMS**

Every one of these Ulmer products is prepared under strict control by experienced graduate chemists and pharmacists in modern, air-conditioned laboratories to insure accuracy and dependability. All are quality items, compounded to meet the exacting standards of the medical profession. They are strictly ethical, not advertised to the laity and dispensed only upon prescription.

We also handle a complete line of wholesale drugs—chemicals, biologicals, ampoules, stains and reagents, volatile oils, drug room supplies, general pharmaceuticals and pharmaceutical specialties of all the leading drug manufacturers. We can supply you with any item in the line of drugs and pharmaceuticals.

●

Send us your Order for any Drug Items you need. Write us for information about any of the many outstanding Ulmer Quality products which you may wish to prescribe.

Physicians & Hospitals Supply Co. Inc.

Minneapolis 15, Minnesota

(Continued from Page 212)

Dr. James Chessen, formerly of Duluth, has been awarded a fellowship by the American College of Surgeons. Dr. Chessen, who is in practice in Denver, Colorado, is a member of the faculty of the University of Colorado School of Medicine and consultant to the Denver University Student Health Department.

* * *

Mid-year commencement at the University was a very special occasion for Dr. and Mrs. Denton Engstrom, of Minneapolis. Dr. Engstrom, who has been studying under the Army Training Program and interning at St. Barnabas Hospital, received his medical degree, and Mrs. Engstrom received a B.S. degree as a medical technician.

* * *

The Minnesota Society of Neurology and Psychiatry held a regular monthly dinner meeting at the Saint Paul Town and Country Club on January 14 at 6:30 p.m. The guest speaker was Dr. Barnard J. Alpers, professor of neurology at Jefferson Medical College. Dr. Alpers' subject was "The Correlation, by Pathological Studies, of Retinal and Cerebral Arteriosclerosis."

* * *

Dr. Alfred H. Wolf, Harmony, has taken over the Minneapolis practice of his brother, the late Dr. William W. Wolf, and will locate there permanently. Until another physician can be secured for Harmony, Dr. Wolf will keep office hours there every Saturday afternoon and evening.

Dr. William Wolf died unexpectedly on December 14.

* * *

Dr. Howard Gray, of the Mayo Clinic, has returned from the East where he attended the meeting of the American Board of Surgery in Philadelphia and addressed the Luzerne County Medical Society at Wilkes-Barre on "Problems Associated with Surgery of the Biliary Tract." While away Dr. Gray attended the Clinical Congress of the American College of Surgeons in Cleveland and participated in a panel discussion on surgery of the stomach.

* * *

Dr. Paul Gamble was elected president of the Freeborn County Medical Society at the annual meeting held at the Hotel Albert in Albert Lea in December. Other officers elected at this time were: vice president, Dr. Leo Prins; treasurer, Dr. Ernest S. Palmerston; secretary, Dr. Paul Persons.

The business meeting, which was conducted by Dr. Daniel L. Donovan, the retiring president, was preceded by dinner at 7:00 p.m.

* * *

Announcement has been made of the following fellowship awards by the American College of Surgeons to Minnesota men: Drs. Everett B. Coulter, Earl H. Dunlap, Paul N. Larson, Reinhold M. Erickson, John R. Paine and Wesley G. Schaefer, all of Minneapolis; Dr. David P. Anderson, Jr., Austin; Dr. Rochfors W. Kearney, Mankato; Dr. Donovan McCain, St. Paul; Dr. Anthony J. Spang, Duluth; and Drs. William H. Bickel, George T. R. Fahlund, Fred Z. Havens, Paul Z. Kiernan and Howard H. Lander, all of Rochester.

With his resignation as city health officer and county coroner in January, Dr. James H. Haines, Stillwater, terminated more than thirty years of public service.

Dr. Haines, who is a graduate of Rush Medical College, Chicago, came to Stillwater in 1895, shortly after receiving his degree. He served as superintendent of the City Hospital for two years, then entered private practice, in which he continued until forced to retire recently because of ill health.

* * *

Dr. Robert Elman, associate professor of surgery, Washington University, St. Louis, Missouri, was guest speaker at the meeting of the Hennepin County Medical Society on Monday, January 6, in the Medical Arts Building. Dr. Elman appeared under the joint auspices of the Medical Society and the Minneapolis Surgical Society.

The business session included nomination of officers for 1947-48.

* * *

Dr. Wilfred M. Akins, now of Red Wing but formerly associated with the More Hospital and Clinic at Eveleth, was guest of honor at a dinner for 150 Minneapolis YMCA campers and their fathers given at the Y's year-round camp—Camp Iduhapi—at Lake Independence.

Dr. Akins, who was located in Eveleth for many years, served as camp doctor at Camp Warren which was operated by the YMCA south of Eveleth.

* * *

Dr. Paul Reed has joined the Lenont-Peterson Clinic at Virginia, Minnesota. Dr. Reed, who is a native of Virginia, is a graduate of the University of Minnesota School of Medicine. Following the completion of his internship at the Minneapolis General Hospital in 1937, he entered practice at Langdon and Rolla, North Dakota, where he remained until enlisting in the U. S. Navy in 1942. Dr. Reed was in service for four years and at the time of his separation was lieutenant commander.

* * *

Dr. Duncan E. Luth, Duluth, was guest speaker at a recent meeting of the West Duluth Women's Club. Dr. Luth's subject was India and Burma, on which he is qualified to speak, having been on military assignment in the China-Burma-India Theatre for fourteen months. Dr. Luth, who was in the Army Medical Corps for almost four years, served as group flight surgeon and chief of obstetrical service of the Romulus Air Base. Later Dr. Luth was assigned as surgeon for the Bengal Wing in Burma and was placed in charge of all medical activities at the Ninth Air Base.

* * *

Dr. Jay A. Myers, professor of Public Health and Medicine at the University of Minnesota, is now associated with five major health groups concerned with the study and treatment of tuberculosis. He is general chairman of the Research Council of the American Chest Physicians; a committee member of the National Tuberculosis Association; a member of the recently established subcommittee of the National Research Council; a member of the committee in the Division of Tuberculosis, U. S. Public Health Service, and a member of the Tuberculosis Therapy Study Section of the National Institute of Health.

* * *

Dr. H. H. Perman, formerly of Moorhead, has purchased Dr. P. W. Demo's practice at Wells, taking over about the middle of January.

Dr. Perman took his medical degree at Washington University in St. Louis. On the completion of his internship at the Minneapolis General Hospital, he entered the U. S. Navy Medical Corps. Since his separation from service six months ago, Dr. Perman has been house surgeon at Abbott Hospital in Minneapolis.

Dr. Demo has re-entered the navy medical service and is now on assignment at the Naval Hospital at Bainbridge, Maryland.

* * *

Dr. Lawrence F. Richdorf, Minneapolis, has been appointed co-chairman with Douglas Misfelt, Saint Paul, of the American Legion Child Welfare program.

A major activity of this committee will be a campaign to raise funds for a permanent professorship in rheumatic fever and research to operate in conjunction with the projected Variety Club Heart Hospital at the University of Minnesota.

Dr. Richdorf attended the Legion's Area D Child Welfare Conference held in Omaha, January 9 through 11, when an appeal was made to other Legion organizations throughout the country for assistance in establishing the proposed professorship.

Dr. G. Arvid Hedberg, superintendent of Nopeming Sanatorium, has announced the appointment of Dr. Reno W. Backus as associate medical director to succeed Dr. Robert Davies, who resigned to take a position in Seattle.

Dr. Backus is a graduate of Rush Medical College, Chicago. He was superintendent of the Methodist Hospital in Peking, China, for fourteen years and while there organized a 100-bed tuberculosis sanatorium. Returning to the United States in 1941, he joined the staff of McGregor Sanatorium in New York. Later he was associated with Glen Lake Sanatorium in Minneapolis, and has been on the staff at Nopeming since July 1, 1943.

* * *

Dr. Ralph Larson, who has been associated in practice with Dr. Marvin R. Williams at Cannon Falls for the past year, has opened offices at Anoka and purchased a home there.

Dr. Larson is a 1940 graduate of the University of Minnesota Medical School. He served his internship at the Orange County, California, General Hospital, then entered private practice. A short time later he was inducted into the Army Medical Corps. As a battalion surgeon he served in England for two years and took part in the invasion of Normandy, where he was wounded and evacuated to England. At the time of his discharge, Dr. Larson had completed fifty-two months of military service.

* * *

Dr. Ernest F. Cowern, North Saint Paul, was guest of honor at an "appreciation party" sponsored by Fellowship Lodge, AF and AM, and members of the East-

ern Star during the Christmas holidays in recognition of Dr. Cowern's forty-three years of service to the community. Among the 400 persons who attended were many of the 1,360 babies Dr. Cowern has delivered since coming to North Saint Paul in 1903.

Dr. Cowern graduated from Dartmouth in 1902 and practiced for a short time in Vermont and New Hampshire before coming to North Saint Paul. He has been local school physician for many years and still is "on the job."

* * *

Dr. Kenneth A. Peterson, formerly of Saint Paul, has opened offices in association with Dr. Frank D. Gray, of Marshall.

A graduate of the University of Minnesota Medical School, Dr. Peterson interned at the Minneapolis General Hospital and was resident physician at the Midway Hospital in Saint Paul for the two years prior to his entry into the army. His military assignments included duty at Northington General Hospital in Tuscalusa, Alabama—a neurosurgical, orthopedic and plastic surgery center—and the Regional Hospital at Fort McClellan, Alabama, where he was chief of the outpatient department. Dr. Peterson was separated from service last fall.

* * *

Eighteen new members, fourteen of them veterans of World War II, were admitted to the Hennepin County Medical Society at the meeting on January 6.

The veterans were: Drs. Eugene Edward Aherne, Evrel Arthur Larson, Howard Martin Frykman, Howard Hoffman Groskloss, Donald Ernest Otten, George Werner, Gordon Strom, Vincent Frances Swanson, John Patrick Kelly, Donald Richard Reader, John Lowell Stennes, Eric Kent Clarke, Stanley Guy Law and Clifford Orvis Erickson.

Cook County Graduate School of Medicine

ANNOUNCES CONTINUOUS COURSES

SURGERY—Two-week intensive course in Surgical Technique starting January 20, February 17, March 17.

Four-week course in General Surgery starting February 3 and March 3.

Two-week Surgical Anatomv & Clinical Surgery starting Februarv 17 and March 17.

One week Surgery of Colon & Rectum starting March 10 and April 7.

Two weeks Surgical Pathology every two weeks.

GYNECOLOGY—Two-week intensive course starting March 17, and April 14.

One-week course in Vaginal Approach to Pelvic Surgery starting March 10 and April 7.

OBSTETRICS—Two-week intensive course starting March 3 and April 28.

MEDICINE—Two-week intensive course starting April 7 and June 2.

One month course Electrocardiography & Heart Disease starting February 15 and June 16.

General, Intensive and Special Courses in all Branches of Medicine, Surgery and the Specialties

TEACHING FACULTY — ATTENDING STAFF OF COOK COUNTY HOSPITAL

Address:

Registrar, 427 S. Honore St., Chicago 12, Ill.

Other new members are Drs. Helen Robertson Haberer, John Jacob Kaplan, Raymond E. Buirge, and Donald John Erickson.

* * *

Dr. T. S. Eberley, formerly of Anoka, has entered practice at Benson. A 1937 graduate of St. Olaf College, Northfield, Dr. Eberley took his medical degree at the University of Minnesota in 1941. He served his internship at the Minneapolis General Hospital, then entered the Army Air Force, where he was made a flight surgeon. His assignments during four years in service included twenty-eight months in Europe, with duty in England, France, Belgium, Holland, Luxembourg, Germany, Austria and Switzerland.

At the expiration of his terminal leave on February 15, 1946, Dr. Eberley enrolled at the University for a six months' postgraduate course. Recently he had been practicing in association with Dr. James J. Warner at Perham.

* * *

Eight oil paintings which included Rochester scenes and California landscapes, the work of Dr. John E. Crewe, were exhibited in a downtown Rochester store during the first week of January.

Dr. Crewe, who is seventy-four and has been in medicine for half a century, started painting as a hobby about fourteen years ago, but he has never had any instruction. Most of the work has been done during the past few years when his health was such that he had to take things easier.

In all, Dr. Crewe has completed about twenty paintings, some of them in water color, his first media. The work is notable for a fine sense of color. Except for a showing of a few paintings at a physician's hobby show, this is the first time Dr. Crewe has exhibited his work.

* * *

Effective January 1, 1947, Dr. Luverne H. Domeier, formerly of Sleepy Eye, began practicing at New Ulm in association with Dr. Otto J. Seifert, whom he had been assisting for the past several months.

Dr. Domeier is a graduate of St. Thomas College, Saint Paul, and took his medical degree at Loyola University, Chicago, in 1939. Following the completion of his internship at St. Joseph's Hospital in Saint Paul, he took postgraduate work at Wayne University, Detroit, Michigan, where he was granted a fellowship in the Department of Pathology in 1940. He has also been pathologist in hospitals in Pontiac and an instructor at Wayne. His army service includes three years as director of laboratories and internal medicine in hospitals in Florida. At the time of his discharge, Dr. Domeier was a major.

* * *

After an absence of five years, Dr. Charles Vandersluis has resumed his practice at Bemidji. Dr. Vandersluis is a graduate of the University of Minnesota Medical School and interned at the city hospitals in Baltimore and St. Louis. He entered practice at Bemidji in

1935 and for the four years immediately preceding his entry into military service in 1942 was coroner of Beltrami County.

Dr. Vandersluis' military assignments included nineteen months in New Guinea and the Philippines. He was returned to this country for separation from service in November, 1945. For the past year he has been engaged in postgraduate work at the University of Minnesota—six months' study in pathology and six months in disease of the heart and blood cells. Dr. Vandersluis is limiting his practice to internal medicine.

During the doctor's absence from Bemidji, Mrs. Vandersluis and their two children remained at home there.

* * *

Dr. Frank W. Quattlebaum and Dr. Jane E. Hodgson have opened offices at 511-512 Lowry Medical Arts Building, Saint Paul, for the practice of surgery, gynecology and obstetrics.

Dr. Quattlebaum is a graduate of the University of Georgia School of Medicine, Class of '39. His internship and an assistant residency at the Medical Center, Jersey City, New Jersey, were followed by a fellowship in obstetrics and gynecology at the Mayo Clinic.

Dr. Hodgson took her medical degree at the University of Minnesota in 1939 and also served her internship and an assistant residency at the Jersey City Medical Center. While there she was married to Dr. Quattlebaum.

For the past year and a half Dr. Hodgson has been practicing at New Smyrna Beach, Florida, and Dr. Quattlebaum was stationed with the Army Medical Corps at Daytona Beach, nearby.

* * *

New and expanding plans for the Mayo Memorial on the University of Minnesota campus now under consideration call for a 19-story structure which would include a new cancer research institute, a wing for the University's School of Public Health, medical administrative offices, an addition to the University Hospitals, a medical and biological library and a large auditorium.

The estimated cost of the Memorial under the original plans was $2,000,000, of which the legislature had appropriated $75,000 and the rest was to be raised by private subscription. If the new plans are adopted, considerably more money must be raised, and the Founder's Committee is studying possible new sources. Among them are a Federal grant, and another appropriation from the Minnesota Legislature. The Minnesota Cancer Society is considering a separate campaign to raise the necessary funds for the Cancer Institute.

Dr. Donald J. Cowling, Saint Paul, is chairman of the committee, and Dr. George S. Earle, Saint Paul, is secretary.

* * *

Dr. Henry W. Meyerding, of Rochester, has returned from a European trip during which he attended a number of medical meetings and gave several addresses. While in Amsterdam, Dr. Meyerding addressed the Society for Furtherance of Physics, Medicine and Surgery, which was established in 1820 and is the oldest medical society in Holland. He was introduced to the gathering by Dr. Peter Formijne, general president of the society, who was a graduate student in medicine at the Mayo Foundation in 1929 and 1930.

In Paris Dr. Meyerding attended the Congress Francaise de Chirurgie, and was elected an honorary member in the Academie de Chirurgie Francaise, which recently celebrated its one hundredth anniversary. He also spoke at a meeting of the Societe Francaise d'Orthopedic and was elected to honorary membership in this organization.

While in Brussels Dr. Meyerding attended the International Society of Orthopedic Surgery and Traumatology as delegate for the United States, and presented a paper on the "Surgical Treatment of Malignant Tumors of the Bone." He was honored by being elected president of the next Congress of the Society, which will be held in Amsterdam in the fall of 1948.

Dr. Meyerding also assisted at the dedication of a

Among those receiving their medical degrees at the December commencement at the University of Minnesota were: Dr. Melvin Reeves, of Brainerd; Dr. William H. Ryan, of Little Falls; Dr. James H. Kelley, of St. Paul; Drs. John Watson, Peter Habein, Charles Conley and Mark Anderson, Jr., all of Rochester.

Dr. Ryan is serving his internship at the Almeda County Hospital in Oakland, California, and will be there until June.

Dr. Reeves, who has been at the Sheltering Arms Hospital in Minneapolis, serving a junior internship for the past year, will take his senior internship at the Good Samaritan Hospital in Portland, Oregon, and St. Barnabas Hospital in Minneapolis.

Dr. Watson will intern at the Robert Packer Hospital in Sayer, Pennsylvania.

Dr. Habein, who is the son of Dr. Harold C. Habein, Rochester, has accompanied his mother to Tucson, Arizona, where they will spend the winter.

Dr. Anderson, son of Dr. Mark J. Anderson, has gone to California with his parents and will serve his internship at the Orange County Hospital in Los Angeles.

* * *

Twenty-one Rochester physicians were awarded degrees for work done at the Mayo Foundation at the December Commencement of the University of Minnesota, and ten physicians received degrees, in absentia, for work performed in the various fields of the Foundation.

M.S. degrees in surgery were conferred on Drs. John A. Evert, Ellis E. Fair, Robert F. Golden, Chester L. Holmes, Charles S. Joss, Cecil G. McEachern, Wendell L. Nielsen, John H. Remington, F. H. Smith and John Zaslow.

Drs. David T. Carr, Edgar A. Haunz, Mary C. Long, Allan E. Moe and Irwin M. Vigran, received M.S. degrees in medicine.

Dr. John R. Hodgson received an M.S. degree in radiology; Dr. J. J. Hinchey, in orthopedic surgery; Dr. John T. Robson, in neurology and psychiatry; Dr. J. W. Pender and Dr. William N. Hardman, in anesthesiology, and Dr. W. S. Green, in dermatology and syphilology.

Those who received the degrees in absentia were Dr. Brown M. Dobyns, Ph.D. in surgery; Drs. A. F. Castrow, Leonard C. Hallendorf, Jack A. Killins, Henry R. Thomas, M.S. in surgery; Drs. Natalie M. Briggs, Richard N. Kent, Paul V. Morton, and A. S. Mann, M.S. in medicine; and Dr. L. Williams, M.S. in neurosurgery.

HOSPITAL NEWS

Staff members and associate members of St. Joseph's Hospital, Mankato, held their annual banquet and election of officers at the hospital on December 12.

All the incumbent officers retained their positions for the ensuing year by unanimous vote. They are: president, Dr. H. Bradley Troost; vice president, Marshall I. Howard; secretary-treasurer, Dr. Anthony A. Schmitz. The members of the executive committee are Dr. Alphonse E. Sohmer, chairman; Dr. Roger G. Hassett and Dr. George E. Penn.

* * *

Dr. Viktor O. Wilson, Division of Child Hygiene, State Department of Health, in collaboration with an advisory committee of twenty-three members appointed by former Governor Thye, is taking an inventory of existing hospitals and making a study of the total hospital needs for the state. The survey is being made in order to qualify for a share of the $75,000,000 annual appropriation for construction of hospitals which is expected to be authorized by Act of Congress.

* * *

The management of the More Hospital at Eveleth has announced the addition of two members to the staff. They are Drs. Carleton W. Leverenz and Lloyd H. Klefstad, both veterans of World War II.

Dr. Leverenz, who is a graduate of the University of Illinois Medical School, interned at Ancker Hospital in Saint Paul. He served in the Army Medical Corps for five years and was in Japan when the war ended.

Dr. Klefstad, a native of Duluth where he grew up, took his medical degree at Western Reserve University, Cleveland, Ohio. He was in the U. S. Navy for three years, his assignments taking him practically around the world.

* * *

Dr. L. Kenneth Onsgard, who recently joined the staff of Grandview Hospital in La Crosse, Wisconsin, is still practicing at Houston, where he makes his home.

CHECK and DOUBLE CHECK on SICKNESS INSURANCE. J. Weston Walch. Price 25 cents; Special prices in quantity. New York: Public Relations Bureau, Medical Society of the State of New York (292 Madison Avenue, New York 17, N. Y.), 1946.

"Check and Double Check on Sickness Insurance" is a new pamphlet published December 15 by the Public Relations Bureau of the Medical Society of the State of New York. The subject is covered in 133 questions and answers with a complete index. By use of this index any speaker or writer can find, in a few minutes' time, material for a 15-minute talk or an editorial a column in length.

The author, J. Weston Walch, is instructor in Economics and Business Law, Portland (Maine) High School, and manager of the Platform News Publishing Company. He studied the subject of sickness insurance while preparing a handbook for use by participants in nation-wide high school debates. Here he gives what he thinks are the outstanding points in the controversy, from the standpoint of a plain American citizen, just as they impressed him in the course of his own work on the handbook.

Mr. Walch was asked to do the job because this question will ultimately be decided in the forum of public opinion. He is thinking here of what would happen to *him* under compulsory sickness insurance. As an average citizen, he doesn't like it. Legislators already know the doctors don't like it. Here is the evidence that the J. Weston Walches of the country don't like it, either. The last question propounded by the booklet is, "Mr. Walch, in your study of this subject what point strikes you most forcibly?" The author answers as follows:

"I am most interested in my own health and well-being and that of my family. I have tried to examine every important point on the subject of sickness insurance on the basis of how I thought my own interests would be affected. I feel that there are other ways of improving the medical care of the American people without resorting to government compulsion.

"You, the reader, should apply the same test—what will happen to you—personally. Don't take anybody's say-so, not even mine.

"For your own sake, check and double check all the facts on this vitally important subject."

Says the foreword to this pamphlet:

"Free of large masses of statistics, and written in a colloquial style, the author's aim is simplification without distortion. This painstaking work is offered as a handbook for community leaders. For this purpose, a ready-reference index is provided. The pamphlet is intended for editorial writers, radio commentators, ministers, teachers, lawyers and members of Chambers of Commerce, Parent-Teachers' Associations, Women's Clubs, Labor Unions and Granges, as well as doctors called upon to speak on the subject."

CHILDREN IN THE COMMUNITY. The Saint Paul Experiment in Child Welfare. U. S. Children's Bureau, Social Security Administration, Federal Security Agency, Washington, D. C.: Children's Bureau, 1946. Free upon request.

An experiment that has challenging implications for communities in dealing with boys and girls with behavior problems is described in this recent publication of the U. S. Children's Bureau. It tells of the work done and the results obtained in Saint Paul, Minnesota, in bringing all community resources to bear in a "first aid" program for youth in trouble.

This experimental project, which was initiated by the Bureau and developed with the co-operation of social agencies in Saint Paul, and carried on from 1937 to 1943, was confined to a neighborhood of 20,000 persons. The neighborhood was small enough for study purposes and yet large enough to provide a good cross-section of a metropolitan community. It represented a wide range of nationality and of family income. The children involved were typical of those to be found anywhere, their behavior problems presenting the usual run of truancy, pilfering, school failure, inability to get along with other children, and the like.

The idea back of the Children's Bureau undertaking was to see what might be done "early in the game" to get a child and his family the help the community had to offer. The schools, the churches, and youth organizations, such as Boy and Girl Scouts and the like, were involved. So were social and law-enforcement agencies, and the community's health services. All were drawn into a plan which called for their referring to the proj-

ect—The Community Service for Children—boys and girls they knew to be in trouble of one kind or another.

Altogether some 700 children were given individual assistance. For some the project's role was largely that of referring the parents or the teachers or some other interested person to a place or person who could help. The referral, in most such cases, followed upon a diagnosis by the project. But, for some 400 boys and girls much more was done and in many cases over a long and difficult period. In four out of five cases, an improvement was brought about and in a high proportion, almost 70 per cent, a change for the better was made in the situation causing, or affecting, the child's behavior, thus giving promise of a long-run improvement. Significantly, although the juvenile delinquency rate for the city rose, in the section in which the project was operating a decline took place.

The value of the project, the Children's Bureau reports, lies in the fact that nothing was done in St. Paul that could not be done in other communities. Those directing the project simply went into the community to try to make a better use of what was at hand in the way of services for children. What developed that was new was the setting up of a referral center to serve as a "first-aid station," as it were, for boys and girls in trouble. Any community, the Bureau points out, could bring about such a co-ordination of its services for children. In small communities, it adds, the child welfare worker or some other person in a strategic position might well serve as the co-ordinator.

Lacking such a central place, or person, informed about all community resources, those dealing with the youngsters—parents, teachers, clergymen, welfare officials, court officials and police officers—are thrown back upon their own resources. They often do not know how to go about seeking help. The Saint Paul project showed how they could get help, and, as a result, many children were benefited.

Industrial Integration

(Continued from Page 175)

1. Abnormal chest sounds.
2. Abnormal heart sounds.
3. Abnormal blood pressures.
4. The presence of hernia.
5. The nervous system's stability without going into the field of psychiatric medicine.

Finally, either as the result of information gained during a pre-employment examination, or as the result of an industrial illness or accident, the physician must create confidence in the applicant or injured worker. Ideally, the medical industrialist should write to the applicant's personal physician and acquaint him with any pathological processes found. He should attempt to appraise disability in terms of days or weeks or in the degree of loss of function to expect. He should neither undertreat nor overtreat. The industrial physician and surgeon must have a definite objective: to return the injured employe to his former employment as speedily as is in keeping with sound medical and surgical practices.

MOBILE SPEECH CLINIC UNDERTAKES SURVEY

(Continued from Page 189)

patient again, there is no need for further consultation. So after the prescribed medicine is gone, the infected ear is ignored until the child's hearing is impaired; or parents who were advised to "give your child time" to learn to talk give him years while his disability grows more and more impervious to treatment.

But University and Minnesota Association officials are convinced that public education can alert the general population to the vital necessity for early diagnosis and correction of such handicaps. And that, in the long run, is exactly what the Mobile Speech Clinic hopes to accomplish.

BOMBAY TO BROOKLYN

Nature's medicine chest is a worldwide reservoir. From Bombay to warehouses in Brooklyn come the hard, bitter seeds of the nux vomica tree, used as a stimulant and general tonic. The fruits are collected in India by tribal natives, who clean, dry and sort the nux vomica seeds in crude trays before shipment.

Ipecac, the dried roots of the ipecacuanha, a low struggling shrub with emetic and expectorant properties, comes from the moist, woody areas of Brazil, Bolivia and Colombia.

Thyme, the aromatic herb, dots the fields of Italy, France and Spain. Its leaves and flowertops produce a soothing oil used in some proprietary medicines in connection with bronchitis and whooping cough.

The Alps, Pyrenees and Vosges of Europe are speckled with the greenish-white flowers of sweet-smelling angelica and the yellow gentian, or felwort. The seed of the former becomes a carminative and tonic. The gentian root, pulled up in summertime and heaped on the ground to ferment, is a bitter tonic. Also flourishing in these mountains is the poisonous monkshood, prescribed under the name of aconite for fevers and heart conditions.

Purgative plants have similar backgrounds. Senna, a constituent of some laxative preparations, is the sun-dried leaflets of a flowering yellow shrub, knee high, which thrives on the heat of the Nile Valley as well as in India. Arabian senna leaves are picked twice a year, crammed into large palm leaf sacks and transported across the desert by camel back to the market places of Port Sudan and Alexandria.

Aloe, a cathartic whose succulent pale green leaves are snipped open and drained into kettles to produce a dried juice, is shipped in gourd shells from Socotra Island, Africa, and from Curacao.

Jalap, the potent purgative, is the dried, tuberous root of a plant grown 6,000 feet above sea level near the city of Jalapa in Vera Cruz. The roots, having been dried out over the hearths of native Indian huts, have a distinct smoky taste.

Agar-agar, a bulk-producing agent as well as a bacteria culture medium in research laboratories, is cultivated by Japanese deep-sea divers fathoms beneath the ocean surface. This peculiar seaweed produces a mucilaginous substance which is carried up into the dry-cold air of the Japanese mountains to be dehydrated and extruded into long, flat strands.

Frangula, the bark of the European buckthorn shrub, irritant psyllium seeds from the Mediterranean and cassia pulp of the pods from the puddingpipe tree in the East Indies are among other laxative herbs from distant sources.

Cloves, a good mixer with drugs, is a spice made of the dried flower buds of the evergreen clove tree in the Philippines and Molucca Islands. In Zanzibar, natives secure the pungent buds by thrashing the trees with bamboo rods. The cloves are spread out on mats to dry in the sun before being baled for export.

Many of these roots, leaves, seeds and flowers are also used in flavoring foods, as condiments, and in perfumes. Aromatic myrrh, for instance, the sweet-scented gum drawn from myrrh trees in Somaliland, has triple duty: as a flavoring extract, as a perfume and as an antiseptic in dentifrices and mouth washes.—*O.P.I. Bulletin*, August, 1946.

SHOULD VITAMIN D BE GIVEN ONLY TO INFANTS?

VITAMIN D has been so successful in preventing rickets during infancy that there has been little emphasis on continuing its use after the second year.

But now a careful histologic study has been made which reveals a startlingly high incidence of rickets in children 2 to 14 years old. Follis, Jackson, Eliot, and Park* report that postmortem examination of 230 children of this age group showed the total prevalence of rickets to be 46.5%.

Rachitic changes were present as late as the fourteenth year, and the incidence was higher among children dying from acute disease than in those dying of chronic disease.

The authors conclude, "We doubt if slight degrees of rickets, such as we found in many of our children, interfere with health and development, but our studies as a whole afford reason to prolong administration of vitamin D to the age limit of our study, the fourteenth year, and especially indicate the necessity to suspect and to take the necessary measures to guard against rickets in sick children."

*R. H. Follis, D. Jackson, M. M. Eliot, and E. A. Park: Prevalence of rickets in children between two and fourteen years of age, Am. J. Dis. Child. 66:1-11, July 1943.

MEAD'S Oleum Percomorphum With Other Fish-Liver Oils and Viosterol is a potent source of vitamins A and D, which is well taken by older children because it can be given in small dosage or capsule form. This ease of administration favors continued year-round use, including periods of illness.

MEAD'S Oleum Percomorphum furnishes 60,000 vitamin A units and 8,500 vitamin D units per gram. Supplied in 10- and 50-c.c. bottles and bottles of 50 and 250 capsules. Ethically marketed.

MEAD JOHNSON & COMPANY, Evansville 21, Ind., U.S.A.

The cry, the fall, the champing teeth, the tonic and clonic contractures, the incontinence—all may yield to DILANTIN SODIUM. The E.E.G. can trace the pathologic brain wave, yet the epileptic may be spared his terrifying episodes. Powerfully anti-convulsant rather than dullingly hypnotic, DILANTIN SODIUM KAPSEALS* offer to the epileptic a sense of security and an opportunity to lead a more normal and useful life. DILANTIN SODIUM KAPSEALS—another product of revolutionary importance in the treatment of a specific disease; another of a long line of Parke-Davis preparations whose service to the profession created a dependable symbol of significance in medical therapeutics—MEDICAMENTA VERA.

DILANTIN SODIUM KAPSEALS (diphenylhydantoin sodium), containing 0.03 Gm. (½ grain) and 0.1 Gm. (1½ grains), are supplied in bottles of 100, 500 and 1000. Individual dosage is determined by the severity of the condition.

Your Ability to Earn

is your

Greatest Asset

Is your disability policy incontestable?

Does it contain the following clause?

"After this policy has been continuously in force two full years during the lifetime of the Insured it shall become incontestable as to the accuracy of the representations contained in the application and as to the physical condition of the Insured on the date thereof."

No one would purchase life insurance that was contestable. The disability insurance carried on one's income should certainly be safeguarded by an incontestable provision.

Your policy should not be a part of the hazard of disability.

Protect your earning capacity with long term, non-cancellable, incontestable disability insurance.

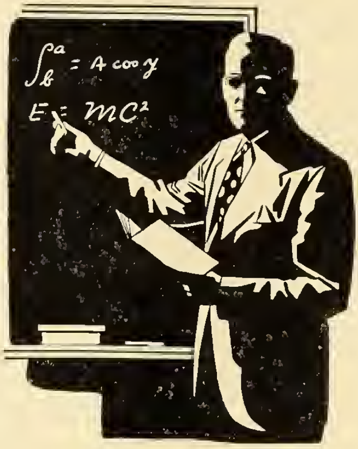
but how potent in *human units?*

Clinical results — not laboratory units — are the true measure of estrogen therapy. And Squibb Amniotin, a truly *natural* estrogen of known safety and effectiveness, is backed by more than seventeen years of extensive clinical use. Amniotin is well tolerated and rarely causes distressing side effects.

Available in a wide range of potencies and dosage forms, Amniotin is excellently adapted to precision dosage.

SQUIBB Amniotin
TRADEMARK

MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858



Molder of Minds . . . . .

Dietary Dub!

His diet is balanced, *yet he is a borderline vitamin deficiency case.* Like many others whose occupations are sedentary and who take little exercise otherwise, his calorie requirements and appetite are so small that he simply does not eat *enough* food to supply adequate quantities of the protective factors. As a result his case record has taken its place in his physician's file along with those of all of the other varieties of dietary delinquents: the ignorant and indifferent, patients "too busy" to eat properly, those on self-imposed and badly balanced reducing diets, excessive smokers, alcoholics, and food faddists, to name but a few. First thought in such cases is dietary reform, of course. But this is often more easily advised than accomplished. Because of this, an ever-growing number of physicians prescribe a vitamin supplement in every case of deficiency. If you're one of these physicians—or if you prescribe vitamins only rarely—consider the advantages of specifying an *Abbott* vitamin product: Quality—Certainty of potency—A line which includes a product for almost every vitamin need—And easy availability through pharmacies everywhere. Abbott Laboratories, North Chicago, Ill.

Trauma and Nitrogen Equilibrium

Recent recognition of the direct relationship between trauma and protein loss has greatly improved the prognosis in postsurgical and post-trauma patients.

Striking and hitherto unsuspected protein loss has been observed in patients with fractures. Excessive urinary nitrogen excretion reaches its maximal point about a week after the injury is sustained, and thereafter slowly diminishes in extent, so that nitrogen balance is restored in approximately four weeks.[1]

In patients sustaining severe burns, the daily protein loss may be equivalent to 400 cc. of plasma.[2]

In a study embracing 23 burned patients, nitrogen balance determinations revealed excessive urinary nitrogen excretion. Nearly all patients were in negative nitrogen balance which was most marked during the first ten days.[3]

It thus appears that protein destruction and loss are prominent and potentially detrimental sequelae of trauma, and that every effort must be made to restore nitrogen equilibrium as quickly as possible to prevent the many deleterious consequences of protein depletion. The recommendation has been voiced that "whenever possible, protein losses or deficiencies should be corrected by oral feeding."[4]

Among the protein foods of man, meat ranks high not only because of the generous supply of protein it provides, but also because its protein supplies all the essential amino acids, making it applicable for every protein need—growth, tissue maintenance, and tissue repair.

P.Z.I.
INSULIN

changing from PZI to GLOBIN INSULIN

When protamine zinc insulin treatment is complicated by post-prandial hyperglycemia, nocturnal insulin reaction, protamine sensitivity, or other difficulties, a change to Globin Insulin often results in the desired improvement. The change is achieved in three steps:

1. THE INITIAL CHANGE-OVER DOSAGE: The first day, 30 minutes or more before breakfast, give a single dose of Globin Insulin, equal to ½ the total previous daily dose of protamine zinc insulin or of protamine zinc insulin combined with regular insulin. The next day, dose may be increased to ⅔ former total.

2. ADJUSTMENT TO 24-HOUR CONTROL: Gradually adjust the Globin Insulin dosage to provide 24-hour control as evidenced by a fasting blood sugar level of less than 150 mgm. or sugar-free urine in the fasting sample.

3. ADJUSTMENT OF DIET: Simultaneously adjust carbohydrate distribution of diet to balance insulin activity; initially 2/10, 4/10 and 4/10. Any midafternoon hypoglycemia may usually be offset by 10 to 20 grams carbohydrate at 3 to 4 p.m. Base final carbohydrate adjustment on fractional urinalyses.

Most mild and many moderately severe cases may be controlled by *one daily injection of 'Wellcome' Globin Insulin with Zinc.* Vials of 10 cc.; 40 and 80 units per cc. Developed in The Wellcome Research Laboratories, Tuckahoe, New York. U.S. Pat. 2,161,198. Literature on request.

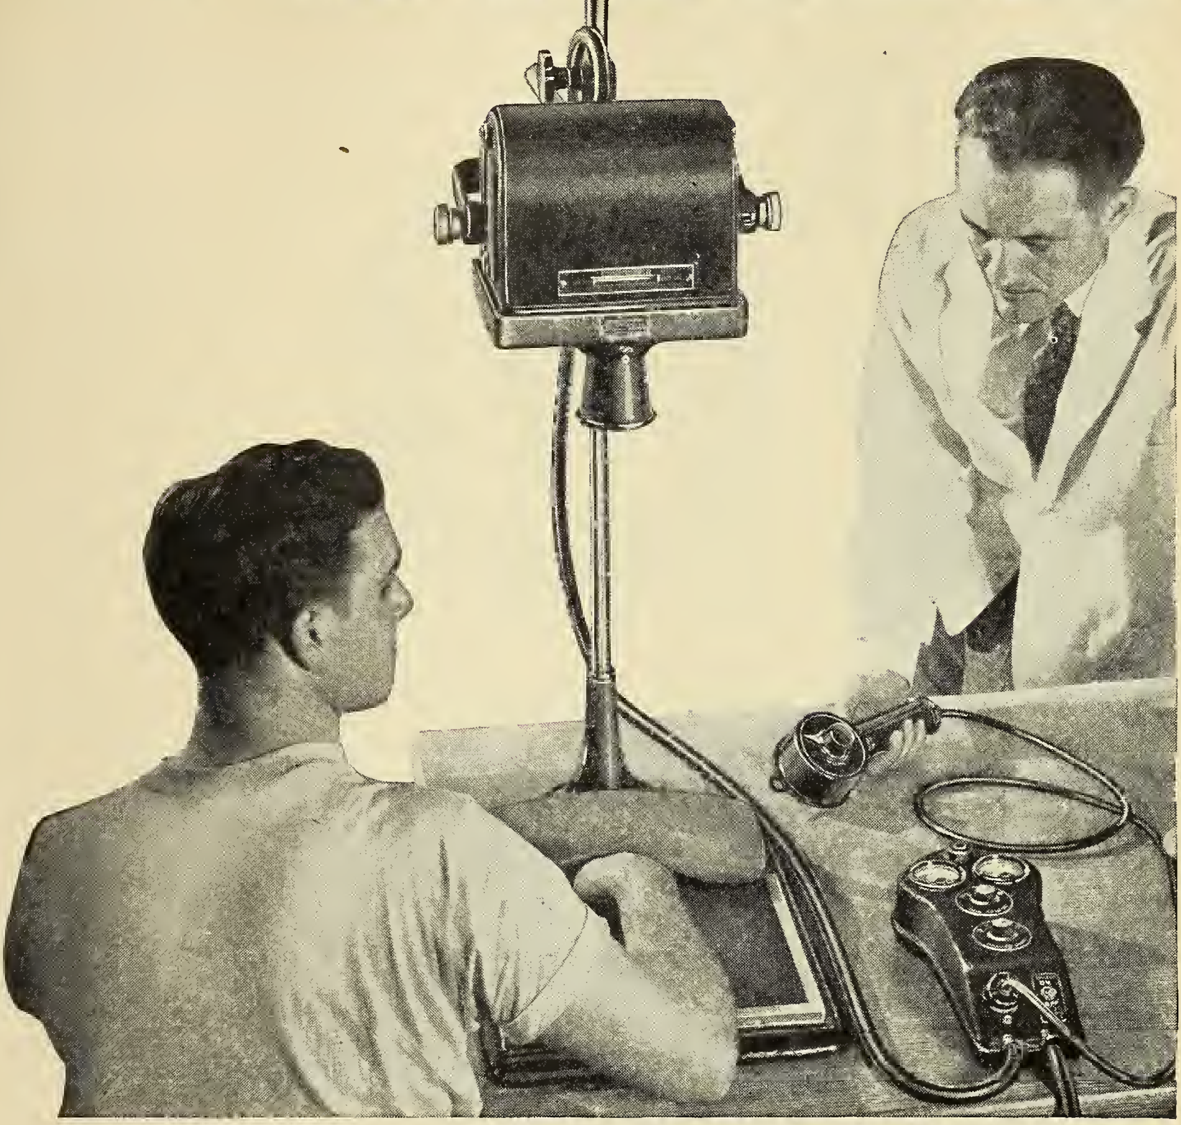
WHY THIS PORTABLE X-RAY FOR YOUR OFFICE PRACTICE?



The fact that thousands of physicians are today using G-E X-Ray's *Model F Portable* is perhaps the most convincing evidence of its recognized value.

You too, would soon conclude that for office x-ray examinations, the *Model F Portable* atop your desk or table greatly simplifies matters; also that the inambulant patient is grateful for this service right in his home.

Within the practical range of service for which this unit is intended, the quality of radiographs it is capable of producing is second to none, regardless of price. You'll also appreciate the high standard of workmanship throughout.

The moderate investment required, and the potential value of a *Model F* in your practice, assuredly justify your investigation. Mail this coupon today.

ETHICS

There can be no middle course between the ethics of the medical profession and the temptations of the market place in the field of anatomical supports. Here the standards of the businessman must be elevated to the standards of the doctor because the customer of the businessman is the patient of the doctor. Anything else is "merchandising quackery." We at Camp have for many decades controlled our distribution throughout the recognized retail institutions which like the doctor have earned the respect and confidence of their home communities. No appeal is used in our advertising approach to the consumer which fails to meet the precepts of the profession. We serve the physician and surgeon by living up to our chosen function of supplying scientific supports of the finest quality in full variety at prices based on intrinsic value. We try to insure the precise filling of prescriptions through the regular education and training of fitters. In cooperation with medical and educational public health authorities we play the role our resources permit in promoting better posture and body mechanics. That is our idea of the practical ethical standards which permit the businessman to solicit the recommendation of the doctor.

Camp Anatomical Supports have met the exacting test of the profession for four decades. Prescribed and recommended in many types for prenatal, postnatal, postoperative, pendulous abdomen, visceroptosis, nephroptosis, hernia, orthopedic and other conditions. If you do not have a copy of the Camp "Reference Book for Physicians and Surgeons", it will be sent upon request.

PLANNING · NOT LUCK

Neo-Iopax

Planning—not luck—is responsible for the pure, crystal-clear solution of NEO-IOPAX for urography. Every precaution known for obtaining a sterile fluid, completely free from foreign particles, is taken with this contrast medium during its production. And when NEO-IOPAX is ampuled it must pass before a corps of specially trained inspectors whose sole task is to detect and reject any solution containing the least visible trace of extraneous matter.

A final inspection by the physician himself before intravenous or retrograde injection is invited by the water-clear glass ampule in which NEO-IOPAX is dispensed.

NEO-IOPAX, disodium N-methyl-3,5-diiodo-chelidamate, is supplied as a stable, crystal-clear solution in 50 and 75 per cent concentrations.

Trade-Mark NEO-IOPAX—Reg. U. S. Pat. Off.

DO YOU KNOW WHAT THESE SYMBOLS STAND FOR?

Rexall
DRUGS

REXALL FOR RELIABILITY

The barber pole is a relic of the middle ages, when barbers professed also to be surgeons and dentists. The pole was originally a red staff, wrapped with removable bandages, hung with dental instruments and topped by a brass lathering bowl. Later, as a concession to sanitation (or possibly to prevent theft), bowl, bandages and instruments were replaced by a painted replica.

The familiar blue and white Rexall sign is a modern symbol of superior and dependable pharmacal service. There are more than 10,000 independent, reliable drug stores, conveniently located throughout the country, which display this sign. It assures you of drugs laboratory-checked for purity and uniformity under the rigid Rexall system of controls—and of selected pharmacal ability in compounding them.

PROTEIN SPARER

Carbohydrates as protein sparers have particular significance in infant nutrition, which requires a high order of efficient utilization of protein for an active metabolism.

CARTOSE* is well tolerated; its content of dextrins in association with maltose and dextrose minimizes gastrointestinal discomfort due to an excessive concentration of readily fermentable sugars in the gastrointestinal tract.

CARTOSE is liquid, facilitating rapid, exact formula preparation. It is compatible with any formula base—liquid, evaporated, or dried milk.

SUPPLIED: In clear glass bottles containing 1 pt. Two tablespoonfuls (1 fl. oz.) provide 120 calories. Available through recognized pharmacies only.

Peptic Ulcer

Stubborn cases call for PHOSPHALJEL

Phosphaljel is unexcelled in the treatment of marginal ulcer. It provides quick relief from pain . . . lays a protective coating over the inflamed mucosa . . . *safely* buffers gastric acidity with no danger of alkalosis or "acid rebound." Phosphaljel permits a liberal bland diet—patients are more contented during treatment, gain strength and weight more quickly.

Phosphaljel provides excellent prophylaxis against seasonal recurrences, as well as protection against marginal ulcer following surgery. It is highly valuable in cases complicated by diarrhea, pancreatic insufficiency or phosphorus deficiency, and is well adapted for continuous buffering by intragastric drip.

Introducing

Borden's

PROTOLAC

A unique high-protein concentrate with 100% biological protein efficiency

Whenever high protein intake is indicated, PROTOLAC provides a unique biologic balance of essential amino acids for optimum protein nutrition.

Tests *in vivo* have shown the protein of PROTOLAC to be 100% efficient — all of the absorbed nitrogen being completely utilizable.

PROTOLAC is a powdered blend of casein, nonfat dry milk solids, lactalbunin, egg albumen, liver protein, hydrolysate of yeast and soy proteins, choline, and 1-cystine.

It is indicated for all conditions requiring high protein therapy including hypoproteinemia, burns, ulcers, pre-and post-operative cases, pregnancy, and lactation.

Administration: 5 tablespoonfuls (approximately 35 gm.) 3 or more times daily, or as prescribed. Recipe suggestions included in every package.

FOR ORAL USE ONLY

Available: In one pound bottles at all professional pharmacies.

Furunculosis .... second in the series: "FACIAL EXPRESSIONS OF SICKNESS"

From a practical standpoint, the use of penicillin orally should be limited to infections in which low doses of parenteral penicillin have proved adequate, for prophylaxis, and for the convalescent stages of such acute infections as furunculosis. Here, when the crisis is past and the fever receded, the administration of 100,000 units of penicillin orally at two or three hour intervals, day and night, for 48 hours is a tested safeguard against relapse. For such prophylaxis, tablets of calcium penicillin, 50,000 units each, are available in bottles of 12.

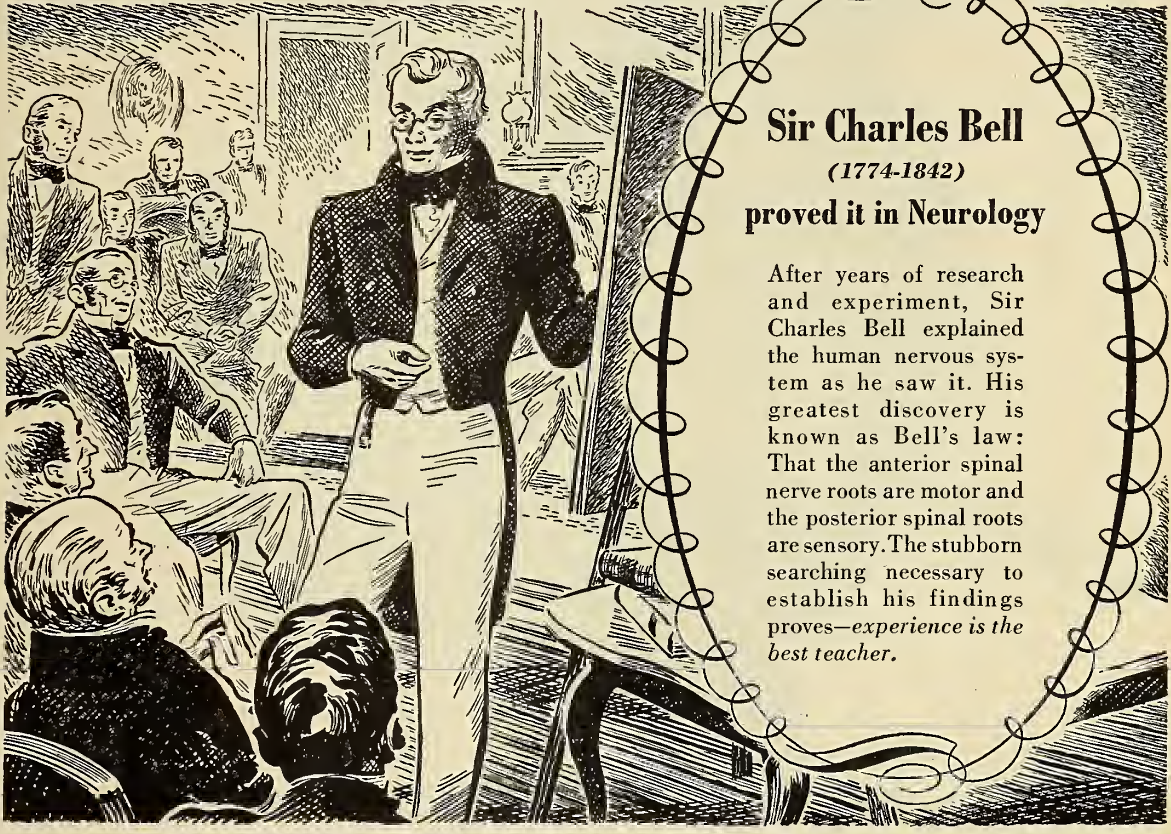
Experience is the Best Teacher



Sir Charles Bell

(1774-1842)

proved it in Neurology

After years of research and experiment, Sir Charles Bell explained the human nervous system as he saw it. His greatest discovery is known as Bell's law: That the anterior spinal nerve roots are motor and the posterior spinal roots are sensory. The stubborn searching necessary to establish his findings proves—*experience is the best teacher.*

Yes, and experience is the best teacher in smoking too!

The wartime cigarette shortage is only a memory now, but that's when millions of people — smoking any brand they could get — learned the differences in cigarette quality.

And, significantly, more people are smoking Camels than ever before in history. But, no matter how great the demand:

Camel quality is not to be tampered with. Only choice tobaccos, properly aged, and blended in the time-honored Camel way, are used in Camels.

UPPER RESPIRATORY INFECTIONS:

management with

PENICILLIN SCHENLEY

Both systemic and topical penicillin administrations have been found valuable in the treatment of infections of the mouth, nose and sinuses, pharynx, tonsils, larynx, and tracheobronchial system.[1, 2] Since respiratory infections often show a tendency to relapse, it is all-important to adhere to the principle established by clinicians widely experienced in penicillin therapy:

give enough-soon enough-long enough

(1) Menefee, E. E., Jr., and Atwell, R. J.: South. M. J. 39:726 (Sept.) 1946.
(2) Woodward, F. D., and Holt, T.: J.A.M.A. 129-589 (Oct. 27) 1945.

PENICILLIN SCHENLEY. Suggested dosage: Intramuscular, 20,000 to 40,000 units every three hours, continued until the patient has been symptom-free for forty-eight to seventy-two hours. Topical, instillation of 3 to 5 cc. of a solution containing 5,000 to 10,000 units per cc., repeated as frequently as indicated in the judgment of the physician.

PENICILLIN TABLETS SCHENLEY. Suggested dosage: 2 tablets (50,000 units each) every two or three hours day and night until all signs of infection have been absent for at least forty-eight hours. This treatment is suitably employed after initial parenteral therapy, and as an adjunct to topical administration.

Specialized skills devoted to the control of bioculture processes insure the dependability of all penicillin products bearing our label.

MYOCHRYSINE

THE consensus of clinicians who have had considerable experience with aurotherapy is that gold, despite its recognized toxicity, is the most effective agent available for the treatment of active rheumatoid arthritis.

The following statements, quoted from the article entitled, "The Use And Abuse Of Gold Therapy In Rheumatoid Arthritis," by Bernard I. Comroe, M. D. (*J.A.M.A.* **128**:848-851, July 21, 1945), constitute an excellent summary of the present position of gold therapy in arthritis:

1 Gold is of no value in any form of joint disease except rheumatoid arthritis.

2 Gold does not benefit all patients with rheumatoid arthritis.

3 Gold is not the final answer to the treatment of rheumatoid arthritis.

4 Toxic symptoms may appear at any time during this form of therapy.

5 From 10 to 20 per cent or more of patients who have received gold therapy relapse after stopping the drug.

6 Extreme care must be used during gold therapy, and the physician must be familiar with the details of such treatment before undertaking this.

7 Injections of certain gold salts in proper dosage may be followed by subjective and objective evidence of improvement in the majority of selected patients with rheumatoid arthritis.

to combat

depression characterized by

"chronic fatigue"

Depressed patients "... suffering from psychomotor inhibition complain of feeling tired, of not being able to get started on their daily tasks, and of an abnormal inclination to procrastinate. They make up their minds that they are going to do a certain thing but they never seem to get to it. Everything seems too big for them ..."*

In the above quotation, Kamman emphasizes "chronic fatigue" as a dominant symptom in the type of depression most frequently encountered in daily practice.

Benzedrine Sulfate is particularly valuable in the presence of "chronic fatigue". It will, in most cases, help to overcome the depression and thus enable the patient to make a sincere and constructive effort to surmount his difficulties.

*Kamman, G. R.: Fatigue as a Symptom in Depressed Patients, Journal-Lancet 65:238 (July) 1945.

Premature, but promising

To the premature struggling for existence, intestinal distention, colic or diarrhea may be insurmountable obstacles. Good care and good nutrition, however, offer promising prospects for life and health.

In the feeding of premature infants, 'Dexin' has proved an excellent "first carbohydrate." Because of its high dextrin content, it (1) resists fermentation by the usual intestinal organisms, (2) tends to hold gas formation, distention and diarrhea to a minimum, and (3) promotes the formation of soft, flocculent, easily digested curds.

Readily soluble in hot or cold milk, or other bland fluids, 'Dexin' brand High Dextrin Carbohydrate is well taken and retained. 'Dexin' *does* make a difference.

'Dexin' **HIGH DEXTRIN CARBOHYDRATE**

ACUTE INTUSSUSCEPTION IN INFANCY AND CHILDHOOD

Report of Fifty-Eight Cases

F. H. MAGNEY, M.D., F.A.C.S.
Duluth, Minnesota

THIS study is based on the cases of acute intussusception coming to operation in St. Mary's and St. Luke's Hospitals during a period of twenty-five years, or from 1921 to 1945 inclusive. There were fifty-six patients who underwent fifty-eight operations. The condition recurred in two cases, necessitating a second operation. Both of these patients survived. The high mortality universally reported indicates that there is a field for further study in order that there be a more general early recognition of this condition, as well as a more early resort to surgery. Only by doing so can we reduce the mortality rate.

No attempt has been made here to determine the etiological factor in each case. Theoretically many factors may play a part, but Ladd and Gross in their series of 484 operated cases were able to determine the cause in only 5 per cent. Smith, in thirty-five cases including all ages, reported that the cause was found in seventeen. It must be noted that it is much easier to find the cause in an adult than in an infant or young child, as in the adult it is usually brought about by some mechanical abnormality or pathologic condition. In infants its occurrence is most prevalent between the ages of four and ten months, which is the time their diet is being shifted from a liquid to a solid one, so it is thought that this is an etiological factor. Its appearance is quite often during or shortly after a siege of acute enteritis. The disturbed intestinal peristalsis at this time may produce the mechanical inbalance that causes the bowel to invaginate. Meckel's diverticulum is accepted as a causative factor. This was found in two of the cases.

The youngest child in this series was seven and a half days old and the oldest twelve years. Seventy-four per cent were less than one year old, and the highest incidence came at six months. All but three were less than three years old. Sixty per cent were boys and 40 per cent girls, which is approximately the ratio found in other surveys. Ladd and Gross report 62 per cent males and 38 per cent females.

There are only three main or cardinal symptoms, and there being only three, every physician having to do with infants and children should keep these in mind. They are namely, intermittent colicky pain, vomiting and bloody stools. Seventy-three per cent of the children showed all of these symptoms, and all had at least one of them. If on examination an abdominal mass can be felt, the diagnosis is certain. If in addition to this, a mass is felt by a rectal examination, there should be no doubt that one is dealing with an intussusception. In 60 per cent an abdominal mass was felt, although only in 20 per cent was a mass felt rectally. The latter condition can be found only if the intussusception has advanced well down in the large bowel, which in most cases would indicate that the condition has existed for some time.

Even the early symptoms are severe enough to indicate that the child is seriously ill, and they should suggest the correct diagnosis. I am sure that many physicians have made the diagnosis by having the mother relate the child's actions over

---

Presented before the Duluth Surgical Society and the Duluth Pediatric Society.

the telephone. In most cases the onset was sudden and consisted of colicky abdominal pain lasting only a few seconds and occurring every ten to thirty minutes. Usually the patient is so young that he cannot describe his pain but the parents will note that the child becomes intermittently pale, draws up its legs and cries out. It may utter a grunt during the paroxysms. It may appear well between these spells and even go back to its play. Vomiting is sometimes the first symptom and almost always an early one. As the intussusception progresses and the obstruction becomes more definite, there is pallor, sweating, dehydration, and later, shock. In this series, vomiting occurred in 88 per cent of the cases. Blood in the stool or on the examiner's finger was present in 63.3 per cent although it was noted that it was less likely to be present if the case was seen early. Ladd and Gross report blood passed by 85 per cent of their patients; Gibbs and Sutton report 70.9 per cent. According to our findings the mortality was 30.8 per cent when blood was present and 15.8 per cent when absent, or nearly twice as high in the presence of blood. This differs from the findings of Gibbs and Sutton who report a mortality of 22.5 per cent with melena and 42 per cent without.

Intussusception does not seem to appear especially in a child that is below par or with a history of nutritional disturbances, but rather in a healthy and well-nourished one. There may be one or two normal bowel movements followed in most instances by bloody mucus resembling current jelly. The pulse is usually rapid and there is evidence of pain the lower right quadrant. Even when in a state of shock, the child will thrash around, cry, and show other evidences of having pain. An elevation of temperature was observed in twenty-two cases or 38 per cent. It is sometimes difficult to palpate a mass in a well-nourished child even though a mass is present. It may be necessary to give a general anesthetic to relax the abdominal muscles. If this is done, the operation room should be set up so that the operation can be carried out under the same anesthesia. The mass is sausage shaped, but may be rather ill defined. If the invagination is small it may be located under the edge of the liver and be hard to palpate.

The intussusception may advance through the whole length of the large bowel and even protrude through the anus and look like prolapse of the rectum.

The laboratory findings were not of much value in this series, as the history and physical findings were so convincing in the majority of the cases that the laboratory was not called upon for assistance. This may have been a time-saving factor as the taking of laboratory specimens, their examination, and the interpretation would tend only to delay the operation. Three cases not reported in this series were supposed to have been reduced by enemas. The majority of the Duluth physicians are of the opinion that treatment is strictly surgical, and the so-called conservative methods were not attempted. No evidence was found in the records that the hydrostatic method of Hipsley was used. In the very few cases in which reduction was attempted by methods other than surgery, a barium enema was used under fluoroscopic observation. Surely no method of this nature should be used if the

TABLE II. OPERATIVE PROCEDURE USED AND ASSOCIATED MORTALITY

Operation	Number	Mortality Per Cent
Reduction:		
Reduction only	31	23

Single enterostomy	1	100
Not reduced-serus surfaces sutured at the beginning of intussusception	1	100

TABLE III. DURATION OF SYMPTOMS AND MORTALITY RATE

Duration of Symptoms	Number of Cases	Deaths	Mortality Rate (Percentage)
Less than 24 hours	28	5	18
24 to 48 hours	13	3	23
2 to 3 days	4	2	50
3 to 4 days	5	0	00
4 to 5 days	5	3	60
5 to 6 days	3	2	67

TABLE IV. TYPE OF LESIONS AND RELATIVE MORTALITY

Type	Number	Deaths	Per Cent Mortality
Ileo-ileal	5	2	40.0
Ileo-colic	49	12	24.7
Colo-colic	4	1	25.0

symptoms have been present for some time, as the series showed instances of gangrenous or near gangrenous bowel and in one case a gangrenous Meckel's diverticulum. The latter was resected and the patient recovered. Hipsley does not use his method if the symptoms have been present more than twelve hours.

If a pediatrician is not already in charge of the case or is in consultation, one should by all means be called without delay. There is no one more qualified by learning or experience to evaluate the child's condition and to treat the dehydration, acidosis, toxicity, and even shock, if present, by administering fluids and restoring the electrolytic balance. Blood and plasma may be needed. The dosage of the pre-operative medication should be left to the decision of the pediatrician. In this series, the mortality rate with a pediatrician in attendance was 23.5 per cent as compared with 29.1 per cent without.

Drop ether was the anesthetic of choice, which conforms to the experience of all other studies. Apparently it is safest and gives the best relaxation. All but five children were given ether. Three had local anesthesia plus ether. Two had local anesthesia plus gas and eight had a combination of gas plus vaporized ether.

Only operative cases in which the pathologic condition was verified are included in this study. Most operators used a right rectus incision, no doubt due to the fact that it gives the best exposure to the region of the ileocecal valve, where the most difficulty is encountered in reduction. The most favorable results are obtained if the duration of the symptoms is short, as the bowel is in better condition and the patient is in better condition to stand the operation. The average duration in this series was 34.4 hours. Ladd and Gross report thirty hours, Peterson and Carter thirty-two hours and Robbins forty-five hours.

Extreme care and gentleness must be used in handling the bowel, due to its friability. Several figures are passed into the left side of the abdomen to locate the head of the intussusception. It is pushed back along the colon. Good progress is usually made until reaching the neighborhood of the ileocecal valve. The bowel must then be brought outside of the abdomen. If there is much edema, this can be reduced by warm compresses. The reduction is continued by a gentle milking process, using the whole hand and squeezing the invagination out. It may be necessary to hold the bowel below between the forefinger and the thumb to steady it. The difficulty encountered near the valve is due to the edema of the gut and mesentery. Perseverance and a prolonged gentle pressure seems to reduce the edema, and in most cases where the situation seems most hopeless, success is achieved. At this point, caution must be exercised and traction avoided. Some operators advise the injection of some glycerin between the two serous layers due to its hydroscopic action on the edematous tissue. After the intussusception has been reduced, the bowl must be observed carefully for tears and viability. Small serous tears can be ignored, but if the tear extends into the muscularis it should be repaired. There is always edema, swelling, discoloration and some degree of hemorrhage, but if observed for a few minutes it will be found to improve in color, especially if a warm saline pack is applied. Immediately following reduction the appendix may appear to be acutely inflamed due to edema, but most authors advise against its removal as it adds to the operative trauma and shock. However, in this series, there was only one death among the eleven who were submitted to an appendectomy. In thirty-one (55.2 per cent) of the cases the operative procedure was limited to the reduction of the intussusception, with eight deaths or a mortality of 28.8 per cent. In one case no attempt at reduction was made as the bowel was gangrenous. The patient died on the operating table. In five cases some method of fixation was done with the idea of prevention of recurrence with no deaths. In one case reduction plus appendectomy and fixation was done without mortality.

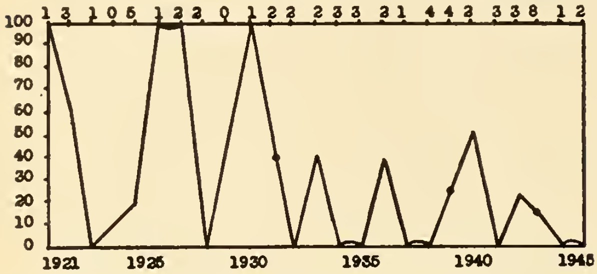

Fig. 2. The mortality rate by years, following fifty-eight operations for intussusception in infancy.

A resection of the bowl was done in seven cases, five of which had a primary anastomosis. There were two deaths, or a mortality of 40 per cent. One had a double enterostomy and one a single, following resection, both resulting in death. Both of these patients were in poor condition before the operation, so the outcome was anticipated. The mortality in all resection cases was 57 per cent which is considered very low. Most reports show a mortality rate of 70 to 100 per cent.

In one case where the reduction was found to be impossible, the serous surfaces were sutured at the beginning of the intussusception and an enterostomy tube inserted. The patient died. A gangrenous Meckel's diverticulum was resected in one case and the patient recovered. No attempt was made to fix the bowel by exteriorization of the appendix as reported by Masson and Judd. Most authors advise against any method of fixation as it only adds to the operative procedure without preventing recurrence. In some cases of recurrence, the invagination of the bowel occurs at a new site the second time.

While it is wise to limit the procedure to a simple reduction, even though it may tax the patience of the operator carrying it out, there are cases in which a resection must be done. In these cases a primary anastomosis was accompanied by the lowest mortality, probably due to the fact that the child cannot stand the loss of the succus entericus. Woodhall has reported the doing of a lateral anastomosis in the Mikulicz operation, thus establishing an immediate continuity of the bowel and preventing the loss of the enteric contents. No such procedure was attempted in this series.

The fifty-eight operations were followed by fifteen deaths, or an overall mortality rate of 25.9 per cent. It is interesting to note the great improvement that has been made in the management of these cases during the last fifteen years.

TABLE V. MORTALITY RATES REPORTED BY DIFFERENT AUTHORS

Author	Per Cent Mortality
Gribsby and Kaplan	20.0
Gordon	22.7
Mayo and Woodruff	23.6
Duluth	25.9
Gibbs and Sutton	30.4
Ladd and Gross	31.2

The first ten years showed a mortality of 46.7 per cent as compared with 18.1 per cent during the last fifteen years. In the last five years seventeen cases were operated upon with only two deaths, or a mortality of only 11.8 per cent.

Gibbs and Sutton report a mortality rate of 30.4 per cent over a sixteen-year period, Ladd and Gross 31.2 per cent, Grigsby and Kaplan 22.0 per cent, Gordon 22.7 per cent and Mayo and Woodruff 23.6 per cent.

The improvement in the results during the more recent years is due to many factors. The early diagnosis and surgery without delay are without doubt of most importance. The improvement in surgical technique plays a great part. The part played by the pediatrician in preparing the patient for operation and caring for him postoperatively is so important that every case should have the benefit of this co-operation. The more recent adjuncts to surgery, such as whole blood, blood plasma, the Wangensteen decompression tube, et cetera, are vital in bringing down the death rate in intussusception.

FINANCING THE ESTABLISHMENT OF A SMALL HOSPITAL

JAMES. A. HAMILTON
Hospital Consultant and Professor of Hospital Administration, University of Minnesota
Minneapolis, Minnesota

OUR discussion is concerned with the establishment of a small hospital, about 50 to 100 beds, in a rural area. It is true many of the principles likewise apply to a hospital of larger size located in an urban center. Recent studies of population indicate that approximately 45 per cent of hospitals in the United States are classified as rural. However, a sizable portion of the rural population is located in areas surrounding urban centers and is not occupied with farming activities. Likewise, the studies are indicating that the rural population would utilize hospital service to the same degree as the urban resident if more facilities were readily available and the cost of such service could be properly financed. Undoubtedly, much of the hospital construction in the next few years will occur in the rural areas.

Launching the Project

For the purpose of this discussion we will assume that there has been sufficient interest in the local community to have resulted in the formation of a small committee requested by the citizens to investigate the possibility of creating a small hospital.

The first step would be to have a survey of the population, health, social and economic characteristics of the area to determine whether there should be a hospital and, if so, what should be the extent of its functions, how large should it be, what facilities are needed to perform the functions as determined, and finally, how can it be integrated with the other hospital facilities of the state program.

A statement of such facts, together with their interpretation on the light of hospital trends, and some analyses of the probability of continued operating support, constitute a real necessity for the launching of a successful project. It tends to keep the local enthusiasm intelligent and within rational bounds. Also, it tends to balance the pressure of local pride with realistic endeavor. If money must be raised for the construction of such an institution, the donors ask very significant questions which cannot be answered without the above data, and such donors usually desire an outside reliable opinion. Therefore, not only is it advisable for intelligent planning, but it also may be considered to be good business in terms of the success of the project.

Such a survey could be conducted by a nearby hospital administrator or a person devoting full time to such consulting services. The nearby administrator usually has the disadvantage of local prejudice, and his recommendations are not so easily accepted, even though he may be a very capable person. The expert consultant who has the benefit of objective distance, also can bring to bear the experiences and conclusions which other communities have experienced outside of the local area. It must not be assumed that such a consultant would always recommend in favor of the construction of a hospital. In fact, I am just completing a survey where we are recommending that no additional facilities be constructed.

The cost of such a survey, including professional fees, will naturally vary with the size of the area, the complexity of the local problem, and the availability of facts. Therefore it may run from $1,000 to $3,000 for a relatively small community. The funds for this purpose can be secured from a local organization such as a lodge, legion, or Rotary Club; from a single individual in the community vitally interested in health affairs, or from local government public funds. The securing of such funds has the additional advantage of giving to the community the first real evidence that the interest for a hospital is deep-rooted—a very necessary fact for the future success of the project.

The next step usually is the formalizing of an organization to serve as trustee in receiving funds and carrying out the objectives. In most cases this is of nonprofit character, and it is well to secure a local lawyer to give advice in the formation of this unit, in order to take advantage of existing state laws which will give freedom from taxation and other privileges. The cost of such assistance is very low. Likewise, it is im-

---

Presented at the annual meeting of the Minnesota State Medical Association, St. Paul, Minnesota, May 22, 1946.

portant to secure some hospital advice as to the best forms of by-laws for the operation of such an institution. Here the American Hospital Association has several suggestions, and again the consultant can be helpful in interpreting these in the light of the local conditions.

The third step in launching the project is the raising of capital funds. The amount necessary will be estimated by the consultant in co-operation with an architect. In these days of high construction costs, it is advisable not to conceive of less than $10,000 per bed. In some rare instances it is possible to do this at the present time for $8,000 per bed. In a few situations the cost may even be higher. Such amounts will construct and completely equip the hospital. Included is an architect's fee which usually amounts to between 6 and 7 per cent of the total construction and fixed equipment cost, and a hospital consultant's fee which ranges from 2 down to 1 per cent depending upon the size of the project.

The capital fund campaign usually includes three phases:

1. A public relations phase which involves the telling to the right people the facts relating to the need and the objectives of the proposed hospital.
2. The securing of promised contributions from a selected group of individuals with means, and from corporations located in the area who will be benefited by the new hospital.
3. The conduct of a general campaign in which everyone in the area may have some opportunity of contributing. Normally the larger portion of the funds comes from large givers in corporations. The general campaign usually yields a very small portion of the total amount.

Many communities have found it worth while to employ outside fund-raising experts. There are several very reliable firms who conduct such campaigns with excellent results. They do not raise the money, but assist the local people in doing so. Many of the theoretical objections to the use of such outside units are so much bugaboo and are unrealistic. They do not use high pressure; they have the benefit of the experiences of many communities; they do guide the local effort and keep it continuously in line with the necessity of activity which is not usually possible through normal voluntary effort. They are trained in developing successful techniques. They usually work on a fixed fee basis, which together with the total costs amounts to about 2 to 3 per cent of the total amount raised. They do not undertake a project unless there is reasonable assurance it will be successful. Most communities feel that "now is not the best time" to raise money, whatever time that may be. If one follows that philosophy, no money would ever be raised for welfare projects. Therefore, this barrier should be overcome from the very beginning.

A considerable portion of funds for recent hospital construction is contributed by corporations. Contrary to the general belief, most corporations in rural areas are not soulless, but reflect the attitude and humanitarian instincts of the human beings who direct them. I could give you many illustrations of corporations who have responded enthusiastically and generously to such hospital effort.

If desirable, it is possible to raise some of these capital funds from tax sources—not only from local, county, and state sources, but from Federal funds available under the new Hill-Burton Act, with which I believe you are acquainted. It is possible to secure about a third of the capital from the funds available under the new Hill-Burton Act. However, it is necessary that the local project be integrated into a state program and that the state authority indicate its approval and priority status.

Construction of the Hospital

This is a period of high construction costs. With the uncertainty of labor costs, contractors are padding their bids. Even then it is advisable to leave additional allowances for a possible rise in cost during the construction period. It is the hope that even though labor rates will not be reduced, that the productivity of labor will be increased. It is also hoped that labor's demands will be stabilized, thus making it possible for the contractors to remove the additional padding. No guess is reliable as to when this will take place.

Also, it is difficult in these days to secure suitable materials with sufficient regularity to produce the kind of hospital one desires. It is hoped, with the removal of priorities and the increased productivity of labor, that materials will be available within a reasonable length of time.

In the meantime, many communities are making specific architectural plans for the development of their hospitals. It is well that a relatively long time be available for such procedure in order that ideas may mature, and that with new thinking, the plans can be revamped as many times as necessary until finally satisfactory. It is advisable to hold in mind that the unit is to be used over a long span of years and that errors in the planning will have a serious effect upon later operation.

Most communities, therefore, are employing not only an architect, but a hospital consultant, and it is my belief that both are necessary to give an economic result. No architect, whether he has done several hospitals or not, is in a full position to keep abreast with changes in hospital operation which may effect a big saving in later operating costs. The qualified hospital consultant is in the best position to reflect such results in the architect's plan.

Operating Funds

In the planning of a new hospital, it is very advisable to plan for the financial operation of the institution in advance of its construction. The most potent influence on the net financial result will be the percentage of occupancy of the proposed institution. Studies have indicated that the smaller the hospital, the lower the percentage of occupancy, which is usually the result of the increased proportion of segregation of patients which is imposed upon the smaller units. Therefore, it is very favorable in the planning of the hospital itself to assure as much flexibility in bed utilization as possible, thus insuring as high a percentage of occupancy and income as can be realized.

Current operating capital should be anticipated to carry the loss of operation for at least six months and perhaps better, for a year. In addition it will be necessary to have some funds for current operating purposes. Therefore it is exceedingly advisable that a budget be prepared in advance. Here again the consultant with his knowledge of hospital operation is in the best position, not only to advise the new Board of Trustees in the operating organization of the hospital, but also to aid in the preparation of the budget.

Normally, it is not possible for the hospital which desires to give some free service to the community to secure its complete income from patients solely. There is an increasing tendency for third parties to pay for patients' bills. In many institutions this is as much as two-thirds of their total load. Such third parties may take the form of the voluntary Blue Cross movement, commercial insurance, and local government authorities. Therefore great care should be taken in making financial arrangements with these third parties which will yield a sufficient income to operate the institution. All of these endeavors are possible in the small community as well as the large. Normally, a hospital of the size we are discussing has as a cost of service about $8 per patient per day. With increased labor costs, the chances are that this amount will increase, and within a relatively short time will amount to $10 per patient per day.

Usually it is necessary for the community hospital to secure some outside financial assistance in its operation. If it is possible to secure endowment funds at the same time as one is raising construction funds, such a situation is ideal. However, this is very rarely possible. Therefore, the raising of operating funds usually takes place after the construction of the institution. For the first few years of its existence, the hospital may secure some of these funds from local governmental sources in the form of an annual subsidy in order that the institution may exist at all. Likewise a local annual drive for the operating contributions may be conducted. Many hospitals have existed on these two sources alone for many years before they were able to secure bequests for endowment purposes.

Summary

The successful establishment of a new hospital must depend upon the possibility of giving good service to the community, primarily through developing a good professional staff, and upon sound planning. If this is done, usually the financial needs are met, provided the facts are properly interpreted to the community as a whole.

To accomplish such results, however, the local people should proceed slowly, and with the advice and guidance of persons experienced in the hospital field.

I am informed by leaders in the rural areas in this country that many communities realize the need for hospital facilities and are prepared to put forth the effort and the sacrifices necessary to secure such community service. Therefore, I have every confidence that the majority will proceed along intelligent lines and that the rural population will eventually have available those hospital services vitally necessary to their full life.

A SHORT COMMENTARY ON THE HISTORY OF THE CIRCULATION

Modern Addenda

F. A. WILLIUS, M.D.
Rochester, Minnesota

THE casual student of medical history associates two famous and well-known historic names with the discovery of the circulation of the blood. He knows that the martyr, Michael Servetus, generally has been regarded as the discoverer of the pulmonary circulation and that William Harvey conceived and described both the systemic and pulmonary circulation, suggested the existence of the capillary circulation and described the essential functions of the heart. Most physicians today consider that Harvey discovered the circulation. I have no intention to deprecate the monumental contribution of Harvey but rather to maintain the accuracy of historical documentation.

In order to do this it is necessary to present the facts as they are inscribed in the records of the past and to supplement the older records with more recent biographic research. In such reexamination of historical data several less prominently mentioned contributors are brought to attention, and particularly one who was introduced to readers only eleven years ago. In presenting this commentary it is not my intention to become involved in the futile controversy relative to priority which is currently being carried on among various medical historians. It is, however, my desire to present certain evidence to the reader which may enable him to conclude that the current concepts regarding the circulation are the product of several noteworthy historic personages living in different eras and in different localities.

According to recent disclosures, the first recorded concept of the pulmonary circulation was that of a famous Arabian physician, Ibn an-Nafis (circa 1210-1288 A. D.). The important information which he contributed became available largely through the recent researches of Meyerhof and of Haddad and Khairallah. Meyerhof learned that a young Egyptian physician, Muhyi ad-Din at-Tatawi presented a thesis on Ibn an-Nafis for his doctorate degree before the Medical Faculty of Freiburg in 1924. This thesis was not published and in all probability would have remained in obscurity had it not been for the interest and continued investigations of the three aforementioned medical historians.

Ibn an-Nafis will be discussed more fully than the other contributors owing to the relatively recent appearance of information concerning him in historical writings even though he is the most ancient of all. He was reared in Damascus but no information is available regarding his parents, his childhood or his early education. Ibn an-Nafis studied the medical sciences under the brilliant teacher and scholar, Muhadhdib ad-Din 'Abd ar-Rahim ibn 'Ali.

Ibn an-Nafis was said to have been a tall man of slender stature, dignified, polite, austere and refined. The biographies of this man, according to Meyerhof, indicate that he was a master of the art of healing and that he had no peer in the acuity of his investigations. He remained unmarried and devoted most of his time to study and writing. Ibn an-Nafis was a prolific writer and did not confine his writing to medical subjects but also wrote extensively on logic, philosophy, theology, jurisprudence, applied law, the Arabic language, tradition and rhetoric.

As was the custom of the day, Ibn an-Nafis wrote numerous commentaries on the works of others but, in addition, wrote three books on medicine. "Kitab ash-Shamil fi't-Tibb" (The comprehensive book on medicine) was an extensive encyclopedia which was never completed and no copy of this work is known to exist today. Another work, "Kitab al-Muhadhdhab fi'l-Kuhl" (The well-arranged book on ophthalmology), is also nonexistent but references to it were found in later works on the subject. The third book, "Kitab al Mukhtar min al-Aghdhiya" (The choice of aliments) was said to be of relatively little importance. A manuscript of this work was known at one time to be in the Berlin State Library.

Ibn an-Nafis' most important work was his commentary on Avicenna's (Ibn Sina; 980-1037) "Sharh Tashrih al-Qanun li-'bn Sina" (Anatomy) because this document contained the first known description of the pulmonary circulation. The exact time of its inscription is not known but Meyerhof believes it to have been about the

---

From the Section on Cardiology, Mayo Clinic, Rochester, Minnesota.

middle of the thirteenth century. At least four manuscripts of this voluminous work have been preserved. Ibn an-Nafis' manuscript, therefore, antedates Servetus' work by approximately three centuries.

Ibn an-Nafis' conclusions regarding the pulmonary circulation were based on indirect observation, speculation and remarkably correct deduction. In the preface of the commentary he stated that the prevailing religious laws and his own innate charity had prevented him from performing anatomic dissections and therefore, he was obliged to study the forms of anatomic structures from the works of others, especially those of Galen. Galen's concepts regarding the heart and circulation were fallacious but were generally accepted as being true for nearly fourteen and a half centuries.

It is most plausible, as contended by Temkin, that Servetus' conclusions regarding the pulmonary circulation were original, for it would have been an unusual coincidence for him to have known of this earlier work. The separation in the space of time by nearly three centuries, the widely separated geographic localities and the great differences in language, strongly support the contention that Servetus was entirely unaware of Ibn an-Nafis' contribution.

Ibn an-Nafis described the pulmonary circulation five times in his "Commentary" and discussed the general physiologic principles of respiration. Man was classified as an air-breathing creature in whose lungs the blood was aerated. He mentioned the alveoli of the lungs which were first actually demonstrated by Marcello Malpighi in 1660.

The following quotations from Ibn an-Nafis' work in translation from Meyerhof's article are of importance: "Therefore, *the blood,* after having been refined, *must arise in the arterious vein to the lung in order to expand in its volume and to be mixed with air* so that its finest part may be clarified *and may reach the venous artery in which it is transmitted to the left cavity of the heart."* Disclaiming Galen's false concept regarding the existence of invisible pores in the ventricular septum, Ibn an-Nafis stated: *"But there is no passage between these two cavities;* for the substance of the heart is solid in this region and has neither a visible passage, as was thought by some persons, nor an invisible one which could have permitted the transmission of blood, as was alleged by Galen." Ibn an-Nafis also stated that the heart was nourished by its own vessels and in this statement at least implied a very early concept of the coronary system.

Ibn an-Nafis' important contribution was, beyond dispute, the one outstanding highlight in the medical accomplishments of the Medieval Era and, owing to its relatively recent disclosure, merits emphasis in historical documentation dealing with the circulation.

The life of Michael Servetus (1509-1553) of Villanueva de Sigena, Spain, has received considerable historical comment and therefore a full account of his tragic existence and death would entail much repetition.[4,9] He was a self-styled theologian, in addition to being a physician, an author, a linguist and a translator, and his religious rebellion found expression during the troubled years of the Reformation.

Servetus was judged to be a heretic by many of his contemporaries and he acquired more enemies than friends. The accusations of heresy were based on the confused and bigoted religious doctrines of his day and his ideas concerning religion certainly would not be considered heretic according to modern, or even semimodern, religious standards. Nevertheless he was convicted of heresy at the insistence of Calvin after an unfair trial, met his death on the pyre after having experienced many humiliations and cruel suffering and became one of medicine's first and most prominent martyrs.

The description of the pulmonary circulation by Servetus was embodied in his famous, controversial, religious work "Christianismi Restitutio" which generally was presumed to have appeared first in 1553. However, Mackall found evidence that this work was written and in circulation by 1546. The "Restitutio" in essence was a disquisition of Servetus' religious philosophy and an outspoken criticism of prevailing theologic views. His description of the pulmonary circulation was used only to illustrate and emphasize a point in discussing the nature of the Holy Spirit. Servetus described the circulation of the blood from the right chambers of the heart through the vessels of the lungs where it was mixed with the air and thence back to the left chambers of the heart. This was his only important medical contribution.

Thus, two entirely unrelated discoveries dealing with the basic and correct concept of the pulmonary circulation are now known to exist in early medical annals. The first occurred approximately in the middle of the thirteenth century and the second, approximately three centuries later. Each contribution, without a doubt was original and Ibn an-Nafis' discovery in no measure detracted from the importance of Servetus' later work.

An Italian anatomist of the Renaissance who described the pulmonary circulation almost correctly deserves mention. He was Matteo Realdo Colombo (Columbus; 1516?-1559) of Cremona, who became Vesalius' (1514-1564) successor at Padua.[2,5] In his work, "De re anatomica," published in 1559, Colombo described the pulmonary circulation but did not explain the details correctly because he accepted certain beliefs of the ancients. He held the view that the veins carried the nutritive blood throughout the body and he also perpetuated Galen's fallacious idea that the liver was the central organ of the cardiovascular system.

By means of vivisection, Colombo demonstrated that the pulmonary veins contain blood but held the erroneous belief that the blood becomes cooled during the process of respiration. He, however, disagreed with Galen regarding the mythical notion that the ventricular septum contains invisible pores and in discarding this belief, Colombo was enabled to understand the general scheme of the pulmonary circulation.

Colombo's work appeared six years after the death of Servetus and some historians are of the belief that Colombo plagiarized the work of the martyr. Colombo was also accused of plagiarizing Vesalius' "De fabrica humani corporis," which was published in 1543. He imitated the title page of Vesalius' work and utilized so many other characteristics of "De fabrica" that from the records of history it has been impossible to clear these suspicions.

Still another important contributor to the discovery of the circulation was the celebrated Italian anatomist, Andrea Cesalpino (1519 or 1524-1603), professor of medicine at Pisa and physician to Pope Clement VIII. Cesalpino's first published work which contained a description of the circulation appeared in the volume "Peripateticarum quaestionum Libri V," which also contained discussions of a philosophic nature. It was published in Venice in 1571 and again in 1593. It is stated, however, that Cesalpino used the term "circulation" in its physiologic sense as early as 1559. Thus, his first publication with reference to the circulation of the blood preceded Harvey's work by fifty-seven years.

For many years a bitter controversy has been waged among medical historians regarding Cesalpino's priority and his rightful place among the discoverers of the circulation. The Italian historians have been particularly irate, not without considerable justification. It is not my desire to enter this controversy but rather to present historical evidence which supports the Italian side of the argument. In a recent interesting and important monograph, Arcieri, who asserts that he has read and studied all the Cesalpinian works carefully, brings forth convincing evidence that Cesalpino had comprehensive knowledge of the circulation. The records of history undisputedly prove the priority of the publication. Corwin, in a relatively recent publication, also emphasizes the importance of Cesalpino's work.

It is important that the following evidence clearly presented by Arcieri be examined carefully. Cesalpino observed the difference in both the structure and the function of the pulmonary artery and vein. His observations also contained a description of the origin, course and size of the aorta and vena cava and the recognition of a difference in the structure of arteries and veins in general. Cesalpino explained that communications exist between the portal veins and the vena cava, he observed the reciprocal relation of cardiac contraction and vascular dilatation, and predicted that an anastomosis (capillaries) exists between arteries and veins. When these various observations made by Cesalpino and his use of the term "circulation" are considered it would be strange if this learned physician had not himself integrated these various observations and understood at least the general scheme of the circulation of the blood.

In 1628, William Harvey (1578-1657) of Folkestone and London, published his famous "Exercitatio anatomica de motu cordis et sanguinis in animalibus.[11,12]" Notes made by Harvey as early as 1616 which are in the possession of the British Museum indicate that even at that time he possessed a clear understanding of the structure and function of the heart and circulation.

It is not known whether Harvey knew of Cesalpino's work. Cesalpino is not mentioned in

Harvey's disquisition while frequent reference is made to Galen, Aristotle, Fabricius and others. Harvey studied at Padua from 1600 to 1605 and during the first three years Cesalpino was still alive. Harvey studied anatomy under the celebrated Hieronymous Fabricius of Aquapendente and it would seem strange if this learned teacher was not acquainted with the writings of a native contemporary in his own field. If Fabricius knew of Cesalpino's work it would seem stranger yet if he had not imparted this knowledge to his students. The problem of language was no barrier to Harvey because he was unusually proficient in the knowledge and use of Latin and his monumental work appeared in faultless Latin. The important question of whether Harvey knew of Cesalpino's work may always remain unanswered.

Harvey's work was not accepted universally by his contemporaries so it is little wonder that the earlier contributions of others failed to either interest or instruct the medical profession of his time. Such celebrated contemporaries as Riolanus, Gassendi and Wormius refused to accept Harvey's clear exposition which was based on dissections, vivisections, observations and lucid reasoning. As already emphasized, the fallacious teachings of Galen endured for nearly fourteen and a half centuries and so deeply were they impressed on physicians that unprejudiced, clear vision regarding the new and correct ideas seemed impossible. Riolanus is credited with the statement that if dissections and observations disagreed with those of the great Galen, then any discrepancies should be attributed to the fact that nature had changed since the day of the great master.

At this point of this commentary it is appropriate to reiterate the generally accepted concepts regarding the heart and circulation which prevailed at the time of Harvey. Earlier physicians accepted the belief that a movement of the blood occurred but, like Galen, they believed that this movement took place in the veins by a process of ebb and flow. Some still held the view that arteries contained air (spirits) while only the veins contained blood. Circulation of the blood had not been universally understood, although as previously pointed out, the general scheme of the circulation was certainly known by Cesalpino. The liver, rather than the heart, was considered to be the central organ of the cardiovascular system, and it was in the liver that the production of blood was said to occur. The prevailing idea was that two kinds of blood were present; one kind flowed from the liver to the right chambers of the heart and to the lungs and then returned to all parts of the body by the veins; the other kind flowed from the left chambers of the heart to the various parts of the body by means of the arteries. One of the crucial fallacies of Galen's beliefs was that invisible pores existed in the septum of the ventricles. Hence, a small amount of blood from the right ventricle was permitted to trickle through to the left ventricle. No definite knowledge of the heart as a propulsive organ designed for the conveyance of blood from the heart and ultimately back to the heart was extant. It was even debated whether the heart is muscular and it was not until 1664 that Niels Stensen (Nicholas Steno; 1638 to 1686), definitely proved that it is. The early physicians considered the pulsations of the heart and arteries to be the result of the alternate contraction and expansion of the air (spirits).

Harvey's exposition was clear, convincing and based on actual proof and offered an intelligible explanation for those who were willing to accept new ideas. His proof was perfect and his disquisition appeared in an era of greater medical enlightenment so that its universal acceptance was only a matter of time. These have been the factors which have stamped this great Englishman as the discoverer of the circulation.

Harvey proved that contraction, not dilatation, of the heart is synchronous with the pulse, that contraction of the ventricles squeezes out the blood and propels it into the aorta and pulmonary artery, that the expansion phase of the pulse is produced when the arteries become filled with blood, that no invisible pores exist in the septum of the ventricles (also proved by several predecessors) and that the only means whereby blood from the right chambers of the heart can reach the left chambers is through the pulmonary circulation. Harvey completed his description of the circulation of the blood when he stated that blood from the left side of the heart is conveyed by the arteries, reaches the veins by small communicating vessels (capillaries) and is then returned to the heart. He could not visualize the small communicating vessels but he postulated

DUODENAL DIVERTICULUM

ARTHUR N. COLLINS, M.D., F.A.C.S.
Duluth, Minnesota

IN an effort to emphasize the importance of duodenal diverticulum, the writer has undertaken to report a case of his own, to review similar cases from the records of local hospitals, and to call attention to the symptomatology and surgical treatment.

In 1710, Chomel first described duodenal diverticulum in a woman dead from apoplexy. The diverticulum contained twenty-two gallstones. Case described it first from the x-ray standpoint in 1913, while Forsell and Kay described the first surgical treatment for it in 1915.

Incidence

In one of our x-ray departments in Duluth, duodenal diverticulum was noted forty times in 1,744 gastrointestinal studies (2.3 per cent). At Stanford University Hospital, during 6,000 gastrointestinal roentgen examinations, it was noted seventy times (1.16 per cent). This is not common, to be sure, but at the same time is not a rarity.

The roentgenologist during gastrointestinal studies not infrequently observes and makes notes of duodenal diverticulum but more often coincidently with other intra-abdominal findings, such as gall-bladder abnormalities, peptic ulcer, carcinoma or other epigastric disorders. Occasionally, duodenal diverticulum stands alone as the single finding to account for the patient's symptom-complex.

Its clinical importance is perhaps not sufficiently recognized. Undoubtedly, many diverticula exist without causing symptoms. Many, unsuspected before death, have been found at autopsy. A diverticulum, small to begin with, probably does not cause symptoms until it attains a size sufficient to develop retention within or mechanical pressure to adjacent structures without.

What relationship, then, has a duodenal diverticulum to the symptoms of the patient? What should be done if it is decided a relationship exists between the lesion and the complaint? The question of its clinical significance has formed the basis of much discussion during the last decade. Groups of cases are being reviewed in the literature, and experiences compared, in a constructive effort to command more exactness. No doubt operations have been done for gall-bladder disease or ulcer when, in essence, a missed diverticulum was at the root of the patient's trouble. Beals, in a study of forty-one cases of duodenal diverticulum seen in his x-ray work, found that about 36 per cent had received surgical treatment for gall-bladder disease or had x-ray evidence thereof.

Diagnosis begins with a careful review of the patient's history, his complaints and the length of time involved. The following case is presented.

Case Report

A man, aged fifty-seven, a construction worker, presented himself complaining that for the past two years he had had epigastric distress after eating, which had been gradually becoming worse. It seemed to him to be gas pressure, for he obtained some relief by belching. Some foods distressed him more than others. Onions, potato chips, cabbage or fried foods were the worst offenders. The distress seemed worse at night. No relief was obtained by taking milk or alkalis, and he found no food which relieved the burning and boring pain. He had experienced no hematemesis or bloody stools. He had lost about ten pounds in weight in the preceding eight months.

On examination he was found to be a man of strong muscular build. Heart and lungs were essentially normal. The blood pressure was 120/80 and his pulse was 68. No tenderness was elicited over the epigastrium or elsewhere in the abdomen, and no mass was palpated. There was a small reducible left inguinal hernia. The extremities were not abnormal. Laboratory findings included essentially normal urine, a hemoglobin value of 89 per cent, erythrocytes numbering 4,640,000, and a white blood cell count of 7,850.

The x-ray studies of the gall bladder and gastrointestinal tract revealed (Fig. 1) "a poorly functioning gall bladder, no evidence of stones, and a negative stomach and duodenal cap. A diverticulum of the second portion of the duodenum was demonstrated, which had an area of decreasing density due either to retained food from a previous meal or to a polypoid growth within the diverticulum. It should be kept under observation, especially if there is blood in the stool, and the advisability of surgery should also be considered in view of these findings. A single film of the abdomen, forty-eight hours after ingestion of the barium meal, shows no evidence of any barium remaining in the diverticulum. Most of the barium has been expelled."

Presented before the Duluth Surgical Society December 26, 1946.

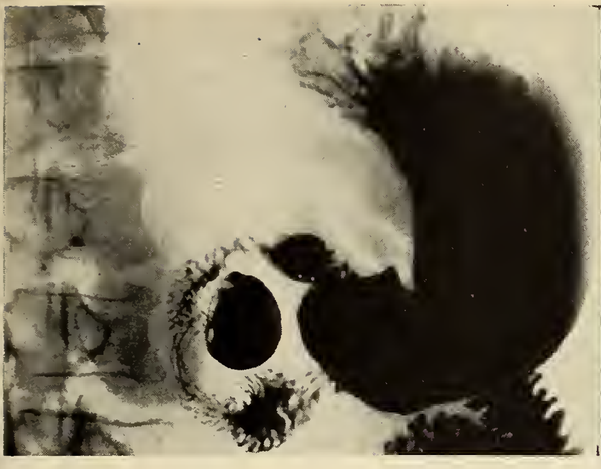

Fig. 1. The x-ray shows a normal stomach and duodenal cap with a large diverticulum of the second portion of the duodenum.

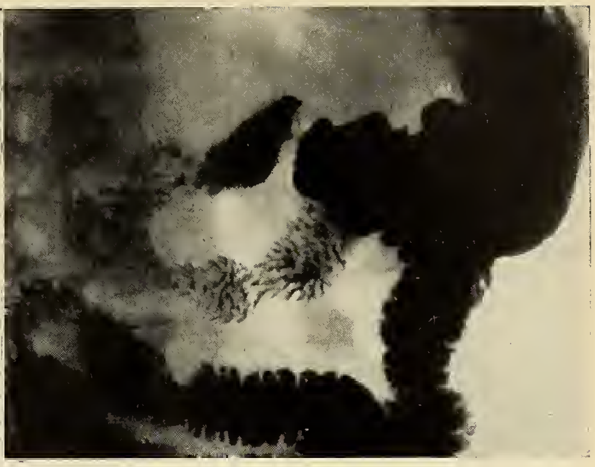

Fig. 2. This x-ray, taken six months after the removal of the duodenal diverticulum, shows a normal appearing duodenum.

In the absence of positive diagnostic findings to account for the man's persistent complaints, aside from the diverticulum, exploration was advised. At the operation, there was found a soft gall bladder and no palpable lesion of the stomach. After considerable search in the second portion of the duodenum, the sac of the diverticulum was found posteriorly. It was rotated anteriorly, clamped at its neck, and removed with a cautery. The stump was sutured and then overcast with interrupted silk sutures.

Postoperatively, a naso-gastric tube was used for decompression of the stomach. A transfusion of 500 c.c. of whole blood was given, supplemented by saline with glucose or by distilled water with glucose. On the fourth day the naso-gastric tube was discontinued, and water in small amounts was allowed by mouth.

The laboratory reported the diverticulum to be lined with normal mucosa without significant inflammatory change.

The man took a vacation and at the end of eight weeks returned to his regular duties. He has worked steadily up to the present time, about six months after the operation. He feels fine, has no pain, and his old trouble has ceased. He is on an unrestricted diet without discomfort. He has gained 20 pounds in weight. An x-ray check-up and report six months after operation was as follows (Fig. 2): "Films of the stomach following the ingestion of the barium meal show the stomach and duodenal cap to be within normal limits. The large diverticulum of the second portion of the duodenum has been resected and the duodenum appears to function normally."

Review of Cases

If it is true, as has been stated, that diverticulosis is noted on roentgen examination with relative frequency, we are faced then with the problem of sorting out and fixing our attention upon those cases in which a duodenal diverticulum is accountable for symptoms disabling to the patient. These diverticula are not all harmless by any means. Malignancy, ulceration, and perforation of a diverticulum have been found to be serious complicating factors. A case of spontaneous rupture of a duodenal diverticulum was described by Beaver in 1938, and similar episodes were described by Boland and Monsurrat. Gallstones have been found within a diverticulum. Hare and Cattell discuss the subject of duodenal diverticulum simulating gall-bladder colic. Sinister factors, therefore, are sometimes linked with this condition, and a differentiation is called for.

Twenty-three cases of duodenal diverticulum have been collected from the records of St. Luke's and St. Mary's hospitals in Duluth, and these involved thirteen males and ten females. There was one child, three years of age, who on x-ray examination showed a diverticulum of the second portion of the duodenum. The rest of the patients ranged in age from thirty-seven to eighty-eight years. Twenty of the twenty-three patients were fifty years of age or older. Ten were over sixty years of age. The overwhelming majority were in the older age group.

Nineteen of the twenty-three patients complained of epigastric pain. Of the remaining four, one patient, aged fifty-one, had aching pain in the left chest and left upper quadrant, worse after eating, with a history extending back fifteen years. The x-ray study was not typical of ulcer, and the patient was not treated surgically.

One patient, aged seventy, had sharp pain in the upper right quadrant, and the history extended back many years, with nausea and vomiting and diarrhea by spells, and with weight loss. X-ray examination showed a duodenal diverticulum in the second portion. The patient was not treated surgically.

One patient, aged seventy-eight, had constant severe pain in the umbilical region for a period of one month, with tenderness, vomiting and loss of weight. X-ray showed a duodenal diverticulum in the first portion. No operation was performed. At autopsy, cholelithiasis and carcinoma of the pancreas were found.

The fourth case without epigastric pain was that of the child referred to above.

As to the nature of the pain, three patients complained of burning pain, three of cramp-like pain, three of sharp pain, and seven of dull aching discomfort. Gas was mentioned as distressing in nine cases, and bloating or fullness in six cases. In eleven cases, the history extended back one year or more. In nine cases, the history extended back "for years." One patient, a man, seventy-two years of age, had attacks for thirty-five years of epigastric burning pain and, at times, nausea, vomiting and constipation, but no local tenderness. On x-ray examination a large duodenal diverticulum was visualized, and six-hour retention was observed in the diverticulum. No operation was done. This was the longest history in the group.

Fifteen of the twenty-three patients had tenderness in the epigastrium. One of the fifteen, a man aged sixty-seven, stated the right upper quadrant was the site of his tenderness. He was an obese miner who was admitted for cardiovascular disease, but who on gastrointestinal study showed a duodenal diverticulum. On the other hand, one man of sixty, had no complaint of tenderness but had epigastric distress. His x-ray study revealed a normal gall bladder and a diverticulum in the second portion of the duodenum with six-hour retention. He stated that Sal Hepatica made his pain worse. No operation was done.

Nausea was listed in the group ten times, and vomiting eleven times. Five of the eleven had intercurrent conditions, such as gallstones, ulcer, or carcinoma, as complications.

The diverticulum was localized by x-ray in the first portion of the duodenum in two instances. One of these two patients also had a carcinoma of the pancreas, and the other had had multiple operations on the stomach. The diverticulum was found in the second portion of the duodenum in nineteen cases. When the third portion was involved, the diverticula were multiple. There were three of these, one in a diabetic with cirrhosis and cardiovascular disease, one associated with an inoperable carcinoma of the pancreas, and one with diverticula also in the second portion. In five cases, cholelithiasis was a complicating factor found either at operation or on x-ray report.

Operation was done to ablate the diverticulum in three of the twenty-three cases. One has been described in the case report. One diverticulum, 3.5 cm. in diameter, was clamped, removed, and the stump inverted. X-ray follow-up showed a good result. The third was located in the region of the ampulla close to the ducts and was turned in by plication. X-ray follow-up in this case also showed a favorable result.

Etiology

In Guys Hospital reports of 1893, Perry and Shaw were of the opinion, as quoted by Edwards, that the pylorus is largely responsible for a rise in pressure within the duodenum. That is to say, when there is a peristaltic contraction in the lower duodenum with the pylorus closed, there is produced an abnormal pressure within the intervening loop. Weak areas in the wall, therefore, may be subjected to greater pressure than they can withstand, and a point of local dilitation results. Adhesions and traction in some instances seem to play a part in causation.

Symptoms

Prominent in the symptoms outlined by Edwards and quoted by Nagel is flatulent dyspepsia of a vague type, with a sense of oppression in the epigastrium. The histories often run back many years. There is a dull distress or a burning sensation in the epigastrium frequently following food ingestion. Nausea and vomiting may be accompanying symptoms, with relief of distress. Pearse observed that if there is retention in the diverticulum and at the same time local tenderness, the diverticulum is probably the cause of the patient's symptoms.

Diagnosis

The duodenal diverticulum can be demonstrated by x-ray, and the roentgenologist therefore pronounces the ultimatum. The location of the diverticulum, as to its position in the first, second or third portion of the duodenum, can likewise be stated by the roentgenologist. The size of the diverticulum also should be noted, inasmuch as the large pouches cause most symptoms. A six-hour film to detect retention in the diverticulum is valuable. The presence, location, size, and six-hour retention of a duodenal diverticulum are, therefore, valuable points of interest to the surgeon.

Surgery

These diverticula are not easy of access to the surgeon. Those in the first portion are rare and are most likely the ones removed at the time of pyloric resections or are the ones which become symptomless thereafter. Those in the second portion are the most common and are the ones which may cause difficult surgical problems.

Lawson found that, of fifteen cases in which there was exploration of the abdomen, the surgeon did not attempt to locate the diverticulum in seven because of other findings regarded as the cause of symptoms. In eight cases where search was made for the pouch, it was found in six. Lahey states they have learned from experience that those diverticula which burrow into the head of the pancreas can be dissected only with the greatest difficulty. Pearse describes a method whereby he slits the diverticulum in order to insert the finger into it and thus help in the dissection, and he uses strong illumination to be sure the common duct and pancreatic duct are avoided. Neil MacLean opened the duodenum and through this opening inserted a finger into the diverticulum to aid in separating it from the pancreas. Nagel believes these diverticula should be resected and not inverted. One has to contend with the fact that these pouches may be collapsed when the surgeon is searching for them, which adds to the difficulty of locating them. Those diverticula beyond the second portion are more easy of access and may often be approached from below near the ligament of Treitz.

Prognosis

While few of these diverticula require operation, it is encouraging that 80 per cent of those treated, according to Morton, are relieved of their symptoms. Beals makes the significant statement that if duodenal diverticula were as accessible to the surgeon as is the appendix, we should soon learn more exactly the relationship between these pouches and the attendant symptom-complex.

Summary

Surgical treatment is indicated for a small percentage of duodenal diverticula. The larger ones are the chief offenders. Their clinical significance should be given careful consideration. If a duodenal diverticulum is associated with a diseased gall bladder or a peptic ulcer, it should be evaluated as to its possibile contributing nature in the patient's complaint.

The author reports a case treated, and twenty-three hospital cases reviewed, most of them in the age group over fifty. Three were treated surgically with good results. In the roentgen study, the presence, location, size, and six-hour retention are important. The surgical experience of various authors is herein discussed. The prognosis is encouraging unless serious complications exist.

OFFICE PROCTOLOGY

A. H. BORGERSON, M.D.
Long Prairie, Minnesota

THE scarcity of hospital beds and the insistence of patients who have no time to stay in hospitals have combined to persuade us to undertake an increasing amount of rectal surgery in the office. Our methods of rectal treatment for ambulatory cases, and a new needle for retrograde injection of combined hemorrhoids, were presented to the Upper Mississippi Medical Society, May 11, 1946. Credit should go to Drs. Buie and Smith of Rochester, Drs. Fansler and Anderson of Minneapolis, and Dr. Frank Yeomans of New York, whose techniques have been modified to suit our purposes. These gentlemen have courteously entertained me at their clinics, and their publications have been freely consulted.

The rectal mucosa ends at the pectinate line which is marked by the anal papillae, the pointed upward extensions of the anal skin, above which extend the columns of Morgagni and between which lie the pockets of the anal crypts. Innervation above this line is autonomic and insensitive to ordinary pain stimuli. The skin below this line is supplied by peripheral nerves and is exquisitely sensitive. Branches of the internal pudendal nerve leave Alcock's canal as it crosses the obturator internus muscle just above the ischial tuberosity, and course medially through the ischiorectal fossa to supply the anal skin and the external sphincter. This makes it possible to anesthetize the anus by a nerve block, using the tuberosity as a landmark. As this does not block the autonomic supply of the internal sphincter it is also necessary to infiltrate, fanwise, on both sides of the sphincter in cases requiring complete relaxation. This thickened terminal portion of the circular muscularis of the rectum is in constant tone, except when reflexly relaxed during defecation peristalsis, and is aptly dubbed the "responsible" sphincter, in contrast to the external or "social" sphincter, loss of whose voluntary control results in musical and olfactory phenomena at embarrassing moments.

Rectal treatment must be preceded by a complete history and physical examination, with routine check on blood and urine. Carelessness in this respect saves no time in the long run, but invites disaster for the patient and embarrassment to the surgeon. It is not pleasant to discover rectal carcinoma in a patient who continues to bleed after his piles have been eliminated, or diabetes in a woman whose pruritis was not alleviated by injection treatment, or tuberculosis in one whose fistula has recurred. The treatment of piles by any method in the presence of a cirrhotic liver or an obstructing pelvic tumor is a light occupation. They will promptly recur.

The next step is always a careful digital and proctoscopic examination. Most rectal carcinomata can be felt with the lubricated finger, and all lesions below the sigmoid flexure can be seen through the proctoscope. Proctoscopy can be done on any examining table by using the knee chest position. The scope is introduced past the sphincters with the obturator in place. When the obturator is removed and replaced by the light, the rectum will balloon up as a result of the vacuum created by the falling toward the diaphragm of the abdominal viscera. This is safer and simpler than bulb inflation, which is seldom necessary. Next the instrument is gently advanced, under direct vision, past the valves of Huston and the rectal ampulla, to the terminal sigmoid. Although any lesion may be seen during introduction, a systematic inch-by-inch survey of the entire circumference is made as the instrument is withdrawn. Long applicators are used to wipe away any flecks of blood, stool or mucus, as these cling more readily to diseased portions than to the normally smooth and slippery mucosa, and may conceal the very lesion being sought. Biopsy may be taken with alligator forcepts or the diathermy loop. Bits of loose tissue are picked up on a wet applicator. Bleeding may be controlled by fulguration, applied with discretion to the anterior rectum above the cul-de-sac, where perforation can open the peritoneal cavity. X-ray examination of the rectum is superfluous and futile, but it is still our best means of visualizing the rest of the colon.

Our patients are told that piles are caused by standing upright on their legs. Since there are no valves capable of supporting the vertical column of blood in the erect trunk, the greatest pressure falls on the veins in the lower rectum.

The straining and milking down effect of passing hard stools blows up the weaker veins into bulbous varicosities, which are piles. This explanation promotes an understanding of the need for periodic checkup to catch recurrences in their early stages, and encourages co-operation in the establishment of proper bowel habits. The loose areolar tissue, containing the venous plexus, beneath the rectal mucosa permits this lining to move freely during defecation. If a large varicosity is extruded beyond the sphincter, it may be prevented by spasm from retracting. Venous return is shut off, and passive congestion is followed by edema, extravasation and painful inflammation, and there results a prolapsed thrombosed internal hemorrhoid. In combined piles, where the varicosities extend beneath the pectinate line into the subcutaneous fat, the thrombus may extend into the external portion.

Prior to thrombosis, the complaints are bleding, protrusion, an aching but not severe pain, or a continued sense of fullness after defecation. The piles are better seen than felt, as submucous varicosities just above the pectinate line which elevate the mucosa into pink to purple, soft, bulbous masses which bleed easily on abrasion.

Piles are best treated by injecting 5 per cent quinine and urea hydrochloride in 2 per cent procaine into the loose areolar tissue surrounding the varicosity, not intravenously. Enough solution to distend the pile, without blanching, is injected, usually 1 or 2 c.c. into each of one or two hemorrhoids at a session. The pile is engaged in a Hirschman speculum, wiped clean, painted with antiseptic, and the solution injected through a tonsil needle on a Luer-Lok syringe. Much smaller amounts of 5 per cent phenol in cottonseed oil are used in patients who react unpleasantly to quinine. The effect is to tighten up the areolar tissue through fibrosis, thus obliterating or supporting the veins and also fixing the mucosa more tightly to the muscularis, an effect which finds its further application in the similar treatment of mucosal prolapse.

External piles are not injected because they are not troublesome, unless thrombosed, and because injection through the perianal skin is a very painful procedure. Their management calls for an occasional incision to shell out a thrombus, or the clipping off of a residual skin tag.

Combined piles may be injected with a retrograde needle (Fig. 1). These needles were first made to the authors specifications by V. Mueller of Chicago, in 1942. Subcutaneous varicosities may be as successfully treated as those beneath the mucosa. Tissue reaction to quinine and urea hydrochloride is the same. The oily solution has not been used in the subcutaneous fat for fear of fat necrosis. Injection of external piles has never become popular because of the pain incident to transcutaneous injection. The retrograde needle was designed to meet this objection. Using a side-slotted speculum of the smaller Fansler type, the needle is introduced, retrograde, into the hemorrhoidal mass above the pectinate line. This muco-cutaneous junction is freely mobile over the varicosity, which extends beneath it under the perianal skin. The submucous portion is first distended, then the needle is advanced outwardly, blowing up the tissue space beneath the crypts and papillae as it progresses into the subcutaneous portion of the pile, and finally injecting there a quantity sufficient to distend moderately the external portion of the hemorrhoid One must be careful not to puncture the skin or to raise an intracutaneous wheal, as this will result in the painful reaction the technique is planned to avoid. When the injection is completed, the needle is pushed back into the rectum to disengage the point, keeping the needle in the slot and the speculum farther within the rectum than the needle point. The point is then rotated away from the slot, where it may be easily withdrawn without hooking up the mucosa.

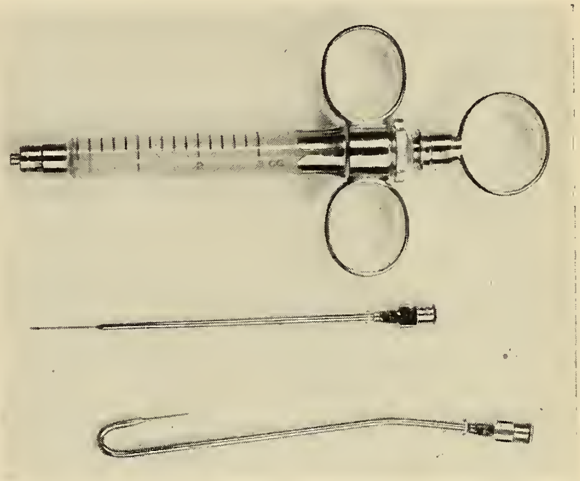

Fig. 1. Syringe and retrograde needle for injecting external hemorrhoids.

A thrombosed pile may be easily treated in the office under procaine block. If the sphincter is adequately relaxed and dilated, a speculum is rarely needed. The thrombosed mass is grasped at its upper pole with Ochsner Forceps, pulled down, and a ligature of fine chromic gut is passed through the mucosa and about the submucous vessels just above the proposed site of excision. This suture is tied and left long. It should include all the tissue down to the sphincter but should not bite into the muscle. An ellipse of mucosa is excised, extending from just below the ligature, over the clot, to the perianal skin just without the anal verge. This extension is important, as it insures drainage and guards against the formation of infected pockets, perianal abscesses and consequent fistulas. The thrombus is cleaned out, the wound sprinkled with sulfonamide, and the long end of the ligature continued downward as a hemostatic, locked suture, closing the wound to the anal verge but leaving the lower end wide open. A vaseline gauze strip is placed over the wound and secured by tying it into the ends of the ligature. There is usually no difficulty with bleeding, but if any spurting vessels are encountered they should be separately secured by mattress ligatures before starting the closure. This avoids the accumulation of a hematoma which could be more distressing than the original thrombus.

The patient cleanses the anus with soapsuds after each stool and applies an external dressing of sulfathiazole ointment. Hot sitz baths alleviate postoperative distress and promote clean healing. On the third day, if there has been no stool, an oil enema is given. The gloved finger is inserted, the wound cleansed, loose sutures removed, and the wound painted with gentian violet. This is repeated twice weekly till healing is complete, usually in about three weeks. The remaining piles are injected during this healing period. Usually no sedatives or anesthetic ointments are required. Mineral oil is seldom used, as the dilating effect of a soft, formed stool is desired. A pint of water before breakfast and a regular morning stool habit are insisted upon, supplemented at times by such a bulk and jelly producing preparation as agar, psyllium or karaya. Any residual varicosities are treated after a month's interval, and a final checkup after six months advised.

Rectal fissure should be suspected whenever painful defecation is followed by a severe, toothache-like pain. The tormented victim postpones the ordeal until the stool is inspissated and impacted, when, finally, its passage is forced by a cathartic or an heroic effort. These diamond-shaped ulcers are usually found between an external skin tag, the socalled "sentinel pile," and a hypertrophied papilla at the posterior anal margin. The older ones are indurated, all bleed easily on abrasion, and their pink, inflamed floors are covered with a yellow, viscid exudate, unless it has been wiped off by a recent stool. Sphincter spasm is so marked and sustained as to make proctoscopic examination impossible without anesthesia. Even digital examination may be an agonizing ordeal. A cluster of submucous varicosities is usually found just above the enlarged papilla. The stubborn persistence of these ulcers in the presence of hemorrhoids suggests comparison with varicose ulcers of the leg. Permanent healing is more likely if the piles are eliminated. Fissure occurs most often at this site because the shelving forward of the posterior rectal wall directs the impact of the descending stool against the least elastic portion of the circumference, where the decussating fibers of the sphincter are firmly attached to the fibrous coccygeal tendon.

Many recent rectal abrasions heal with no treatment. A few recent fissures have healed after digital stretching and the application of silver nitrate. Few patients will permit such treatment in a well-developed fissure. The first essential in proper treatment is to secure sustained anesthesia and relaxation. One per cent Diothane or such an oily anesthetic as Zylcaine is used to block the sphincter on both sides. The sphincter is gently and gradually stretched as it relaxes, taking care to tear neither muscle nor mucosa. Mucosal lacerations and extravasations in or about the sphincter cause anal stenosis with consequent persistence of the fissure. The bivalve retractor-type Smith speculum gives adequate exposure. If the fissure is recent, soft, small and elastic, excision is unnecessary. The internal pile above is injected, and the granular, indolent ulcer surface is pooled up to the point of blanching with the same quinine solution with the deliberate intent to produce a superficial slough down to healthy, fresh tissue. The same result may be achieved by diathermy coagulation, but the author prefers to avoid this method. It is very easy to cook the tissues a little too deeply, and a well-baked sphincter tends to be replaced by a fibrous, contracting scar.

If the fissure is large, chronic, or indurated, it should be excised in an ellipse wide enough to include both margins and extending from the hemorrhoid above to just outside the anal verge. The same preliminary ligature and continued suture technique employed in treating thrombosed piles is used, but the dissection must be carried right down to the bare sphincter, where may be seen or felt the so-called "pecten band," an annular zone of fibrosis caused by organization of the inflammatory exudate in the lymph spaces overlying the sphincter. This will not stretch, and must be severed with the scalpel to expose the healthy, meaty and elastic sphincter. The incision is closed to the lower edge of the sphincter, where the mucosa may be tacked down with a pair of interrupted sutures, leaving the lower end open past the anal verge. Dressings and after-care are the same as previously described. One must be particular to maintain dilation until healing is complete. The long-lasting anesthetic may be repeated, if needed, in patients in whom dilation is difficult to maintain.

Fistulas may sometimes be prevented by incising an infected crypt. A bent malleable probe or crypt hook is used to lift up the crypt wall, which is then snipped off under the probe with scissors. A persistent or neglected crypt infection may burrow along the lymphatics to the ischiorectal space, where an abscess forms and is incised, or finally breaks through the skin, establishing a fistulous tract extending from the crypt to the external opening. Early incision is indicated, as it prevents the extensive burrowing which too often results in the extensive, multiple branching fistulas, which are, indeed, a formidable problem. So-called "expectant treatment" entitles one to expect only this unpleasant result. Penicillin in procaine may be used if the abscess is too deep for ethyl chloride refrigeration. Drainage is better promoted by cutting off a corner of a crucial incision than by insertion of a gauze pack. A single strip of vaseline gauze may be inserted to the bottom of the abcess cavity. The finger should be inserted to feel out and break down any loculated pockets. The patient should be told that only the first part of a two-stage operation has been performed. Bleeding and the spread of infection are minimized if incision of the entire tract is delayed until inflammation has subsided and the wound contracted. Hot sitz baths are used after the first, large post-operative dressing. Meanwhile, sulfamerazine and a daily dose of penicillin in oil are useful. Only the simpler and more superficial fistulas should be treated in the office. If a malleable probe can be guided all the way through the fistula, it can be replaced by a grooved director, and the entire tract laid open by a single, straight incision onto the director. The operation is completed by trimming off the overhanging edges to form a gutter. The wound is sprinkled with sulfonamide and filled with vaseline gauze strips. Frequent dressings prevent bridging over, and must be continued until healing from the bottom up is complete. A straight radial incision through the sphincter is sometimes necessary, and heals without incontinence. Severing the sphincter in more than one place at the same time or cutting it obliquely invites this disaster.

Summary

Simple, proved methods for treating most piles and fissures and some fistulae, in the office by ambulatory methods, are described.

A new needle for retrograde injection of combined piles is presented.

HANDICRAFT BOOKS VALUABLE AID TO PHYSICAL THERAPY AMONG PATIENTS

Self-instruction books in various handicrafts are proving more and more important in the mental rehabilitation of hospitalized persons and those suffering from nervous disorders.

The House of Little Books of New York City, publishers of a line of $1.00 and $1.50 arts and crafts books, have made an outstanding contribution to this field. Among their subject titles most widely received by hospitals and mental institutions are: *Fundamentals of Clay Modeling* by R. R. Fiore, *Working in Leather* by Margaret Ickis, and *Fundamentals of Wood Working* by Harry C. Helfman. These books show how to develop satisfying skill in these crafts. Simply worded, with easy how-to-go-about-it instructions—plus scores of illustrations, sketches and examples—they afford hours of relaxation for patients. As a hobby outlet, too, they are highly recommended, for adults as well as for children.

These books may be purchased at leading art, book, and department stores throughout the world, or directly from the publisher, House of Little Books, 80 East 11th Street, New York 3, N. Y. Complete lists available on request.

GETTING THE MOST FROM A PATHOLOGIST

CHARLES W. VANDERSLUIS, M.D.
Bemidji, Minnesota

EVERY year a certain amount of money is wasted on pathologic services. Some think that hospital standards requiring routine pathologic examination of every appendix, gall bladder, and fallopian tube are responsible for a good deal of this waste, inasmuch as the main gain usually is a written report by a disinterested party after the operation has been done. Furthermore, there is little evidence, from the type of tissues submitted for examination, that the certain knowledge of pathologic review acts as a deterrent to surgery. Admitting the questionable need of some of this expense, there is, in addition, a greater and more hidden waste—namely, that the doctor is not always getting the information he could get from pathological examination of his tissues. In some cases, this is due to misinformation from the pathologist but more often to misinterpretation by the doctor.

For example, let us consider the appendix. This vestigial remnant is responsible for a good part of the income of the surgical pathologist, and he sees a good many of them. If a smooth, normal-appearing appendix is submitted to him without a report of the clinical course and the total and differential white cell counts, it is very possible that he will get the impression that the patient may have been operated upon by a hurried doctor. Routinely, he will cut a block or two for the record. When he reviews the microscopic sections and sees nothing unusual, he will have little compunction about making a diagnosis of normal appendix or chronic appendicitis, depending upon the sensitivity of the referring doctor. Whichever diagnosis is made, it is apparent that the intent is to indicate that the operation was, at least, not a medical emergency. However, if the specimen is accompanied by a history of acute onset, rapid progress, and leukocytosis with an increase in neutrophiles, the pathologist will more likely view it with respect in spite of its possibly benign appearance, will choose the sites for his blocks with more care, and, in certain cases, make a smear of the contents of the lumen. He is sensitive about being unable to find disease when there is good presumptive evidence that it is present, but he is calloused to appendices because he sees so many which appear harmless.

A good deal of abdominal surgery has fallen into disrepute with the pathologist. Although he is not a practicing clinician, he has been trained in clinical diagnosis and knows its value. In cases where pathological examination of tissue is not conclusive, he can profitably use clinical facts when making a decision because his record stands, in many cases, as the final diagnosis. To deny the pathologist clinical information is shortsighted. He is usually in a better position to correlate clinical facts with what he sees than is the physician to correlate a description of what the pathologist sees with his clinical finding. That the pathological report is all-important with government agencies and insurance companies in judging the competence of surgical care is, in some circumstances, unfortunate, but the fact remains, nevertheless, that it does hold that position. Apparent discrepancy between clinical diagnoses and pathologic reports is considerable. Even though from 75 to 80 per cent of the inflammatory conditions in the abdomen are due to appendicitis, almost 50 per cent of the appendices submitted for pathologic examination (excluding those removed routinely in the course of other abdominal surgery) are pronounced normal or are given a comforting name. The surgeon can partially correct this discrepancy by being sufficiently specific in his indications for an operation to write them down for the pathologist. Many studies have shown a fair correlation between clinical and pathological data in appendicitis. By making careful clinical records, the operator will seldom have to shrug off a surprise report.

Many uteri are submitted for examination. Those which are normal in size and not accompanied by a clinical history are puzzling to the pathologist. Money is often wasted upon an examination of this type because the surgeon who removes a normal-appearing uterus usually knows more about it than the pathologist who sees it postoperatively. Such an organ should be ac-

---

Read before the Upper Mississippi Medical Society at Ah Gwah Ching, Minnesota, October 5, 1946.

companied by a history. To insure complete fixation, it should be opened by the surgeon beforehand so that the endometrium will be exposed to the formalin. It should be incised exactly through the midline from front to back. Larger uteri should also be cut open in this manner, and tumor masses should be incised in order to allow more complete fixation. A history of the reason for removal, unless the pathologic condition is obvious, always brings a more careful examination and a more considered diagnosis.

Nothing seems to provoke more remarks among pathologists than the receipt of corpora lutea as surgical specimens. Sometimes such an object is the only one removed in a laparotomy, probably as a side excursion from a uterine suspension. As we all know, a corpus luteum is physiological and harmless, and is easily diagnosed grossly. It is rounded and firm and sometimes measures more than an inch in diameter. The wall is yellow and sometimes wavy in outline, and the cavity contains bloody fluid. Its removal is a surgical mistake, and its histological examination is a waste of time. The pathologist makes his slide from a small part of it only for the record. Many small, smooth-walled cysts of the ovary are also removed. These are usually harmless. The distinction between follicular, luteal, and endometrial types can usually be made only on histological examination, and sometimes not then.

Occasionally, thyroid glands are submitted for examination. As a result of clinical study of the patient the surgeon usually pretty well knows the nature of every thyroid which he removes, but he is often disappointed by the pathological report. The main reasons for this diappointment are the shortcomings of pathological examination and the usual circumstance that the pathologist does not have the clinical information which the surgeon possesses. If the patient with a diffusely hyperplastic gland and symptoms of hyperthyroidism has been treated with iodine for some time and the symptoms relieved, the gland on pathologic examination may not be diagnostic of past difficulty. Generally, there are remaining foci of lymphocytes, but the epithelial hyperplasia and reduction of colloid so characteristic of Graves' disease may no longer be apparent. Without a clinical history, the pathologist does not always feel justified in making the diagnosis of treated Graves' disease. This is sometimes disconcerting to the surgeon, in view of the incidence of continuation or recurrence of symptoms in this condition. If a patient with a nodular goiter of some years' duration develops symptoms of toxicity and undergoes thyroidectomy, the gland will show mainly its adenomatous character. Histological evidence of toxicity, at best present only between the nodules and further diminished by iodine treatment, is most often absent. This cannot be taken as proof that the gland was not responsible for symptoms. The pathologist usually makes a diagnosis of nodular or adenomatous goiter, without reference to toxicity. By observing the clinical course, the surgeon must settle that question for himself.

Of most direct service to the patient and physician is the correct interpretation of biopsies. The most frequent specimens of this type are uterine curettings. If only a few curettings are present, the diagnostic probabilities lie between incomplete curettage and postmenstrual or senile endometrium. Malignancy is not to be expected in a small volume of curettings. If a great amount is present, the gross conclusion is that either hyperplasia or carcinoma is the likely diagnosis. Microscopic examination is made in every case, but sometimes all fragments are not sectioned. In order to keep the pathologist on his guard the surgeon should make a thorough curettage and submit all of the tissue free from blood. It is much easier to separate the tissue from the blood before the mixture has been put into formalin. Then, if the pathologist receives a large amount of curettings, he will be more on the alert for malignancy. Along with the specimen, the referring doctor should send a summary of symptoms, menstrual history, and, without fail, the age of the patient.

It is not often that a pathologic examination of endometrium gives the reason for uterine bleeding. If a definite cystic hyperplasia or a carcinoma is found, the answer probably lies here. In most cases, however, the endometrium appears normal and is described according to its stage of development in relation to the menstrual cycle—either proliferative, secretory, or premenstrual. If the endometrium is of the secretory or premenstrual type, it may be assumed that the patient ovulates normally and that a corpus luteum has been formed. This knowledge is of some help because anovulatory uterine bleeding is fairly common in the early and latter parts of menstrual life. Most endometrium removed, however, is found to be in the proliferative stage. This is because normal endometrium in women past the menopause is normally of this type, ovulation no longer taking place. A single curettage showing proliferative endometrium in a cyclic woman obviously does not prove anovulatory bleeding. A second biopsy should be taken two weeks later. Cystic and hyperplastic changes occur almost exclusively in proliferative endometrium of women just past the menopause and are signs of prolonged, unopposed estrogen activity.

Decidual transformation of endometrium is sometimes found on histologic examination. If chorionic villi are found with the decidual cells, the diagnosis of intra-uterine pregnancy is established. If chorionic villi are not found, however, evidence of intra-uterine pregnancy is not complete because uterine endometrium undergoes identical decidual change of pregnancy in 50 per cent of cases of extra-uterine gestation. The finding of advanced degenerative changes in decidua, however, points to aborted intra-uterine pregnancy.

Oftentimes the real answer to the problem of uterine bleeding lies outside the endometrium, and the doctor must assure himself that there is no leukemia, purpura, anemia, ovarian tumor or uterine myoma. The question of a submucous myoma cannot be settled by examination of the endometrium, but the operator might be able to feel a projecting fibroid with his curette. An ovarian tumor, especially in obese women, occasionally escapes earnest efforts at detection by pelvic examination and will only be found by laparotomy.

Cervical biopsies are frequently submitted. Accompanying histories should include the age of the patient, notation of previous pregnancies and the gross appearance of the cervix. If the biopsy is made so that a normal portion of mucosa is included, it may be possible for the pathologist to pick up a precancerous or early cancerous lesion where otherwise he might not be able to say. The specimen should be cut deeply enough to include some of the underlying tissue of the cervix so that the degree of epithelial penetration can be determined. It is of great importance that the biopsy be taken perpendicular to the surface, so that the resulting section will show the epithelium in strict cross-section and not obliquely. The possibility of a section of epithelium being oblique is constantly kept in mind by the pathologist when making a decision between malignant and nonmalignant thickening. Oblique sections are sometimes impossible to read reliably.

The decision between when to biopsy and when to attempt removal of a lesion without knowing its nature is important in many instances. In case of a mass in the breast it seems best, as a general plan, to limit initial surgery to its adequate local removal, unless it is obviously malignant. Pathological examination is probably more useful in saving benign breasts than in causing radical removal of malignant ones. There is less harm in leaving an operation temporarily unfinished in the occasional case than in removing an entire breast and possibly doing a radical operation for a few cysts or fibroadenomata. If the removed mass does prove to be cancer, a block dissection can still be done. Before putting such a specimen into formalin it is desirable to dissect the axillary lymph nodes from it. Finding these nodes by palpation is much easier in the fresh specimen than in a formalized one, in which case the fixed fat and the nodes have about the same consistency. Putting these nodes into a little gauze sack will insure pathologic examination of all of them and a much more accurate prognosis.

The diagnostic procedure to be followed in lesions of the lip depends to some extent upon the treatment intended. Small carcinomas are very satisfactorily treated with x-ray or radium, but they should first be biopsied. It is the practice of some men to biopsy without anesthesia, removing only a little epidermis. Unforunately, some of these specimens are not diagnostic because too little dermis is included for estimation of epithelial penetration, and because so little tissue is present that orientation for a truly perpendicular section is impossible. A lip biopsy should be reasonably deep, even though narrow. Since many early lesions might just as easily be removed as biopsied and radiated, it is just as well to dissect these out with normal tissue on all sides and have them examined. If early cancer is present and no cervical nodes are felt, it is permissible to let the matter rest. In case of a large lesion, a biopsy should first be taken. If the report is that of squamous cell carcinoma, a complete dissection of the tumor and of the submental and subaxillary lymph nodes should be carried out.

The failure to biopsy before removal has often been regretted in tumors of the subcutaneous tissue or muscle. All of these masses should be biopsied as soon as discovered. If they are small and discrete, they can be widely removed at the first sitting. If they are large, however, a biopsy should suffice for the first attack. Many tumors thought to be simple fibromas are, in reality, fibrosarcomas or myxosarcomas with a marked tendency for local recurrence. It is more economical of the patient's tissue to do a wide dissection of a large malignant tumor after biopsy than to perform a routine removal with a practical certainty of recurrence if examination proves the presence of malignancy.

Lymph nodes are often submitted for diagnosis. In case of a suspected lymphoblastoma, the doctor should find out the duration of enlargement of the nodes, the location of those enlarged, size of the spleen and liver, width of the mediastinum, presence or absence of pulmonary involvement, and the nature of the blood picture. Sometimes, in a single node there is poor histological distinction between lymphosarcoma, Hodgkin's disease and leukemia. The physician who wants this distinction made should supply the pathologist with all of the information mentioned above. Since there is a certain overlapping of histological as well as clinical criteria for these diagnoses, it is possible that the doctor will have to be satisfied for the time being with a diagnosis of malignant lymphoblastoma, which is an inclusive term. Some pathologists are now distinguishing reticulum cell sarcoma within the group of lymphosarcomas by the larger and more irregular character of the cells.

In addition to the specific tissues referred to above, which, with gall bladders and uterine tubes, are the most numerous of the surgical specimens, there are tumors of bone, rectum, skin, mouth, ovary, vagina, parotid and intestine. Branchial and thyroglossal duct cysts and fistulas, anal fistulas, cutaneous ulcers and granulomata fairly well round out the list. A history of the lesion and the age and other pertinent facts about the patient should accompany all of these tissues.

Detection of cancer cells in pleural and ascitic fluid is sometimes possible by histologic methods. If it is desired to submit such fluid for examination, a certain amount of preliminary work is necessary. The entire amount should be centrifuged or the cells allowed to settle out in a refrigerator. The supernatant fluid is then poured off and discarded. Smears are made from the sediment and are air-dried. The remaining sediment is then collected and allowed to settle again, or it is centrifuged in order to concentrate as much as possible. The remaining supernatant fluid is discarded and 10 per cent formalin is added to the settled material, which is then sent to the pathologist along with the smears.

Blood smears are often submitted for diagnosis, and usually with too little data. A history of the illness, the hemoglobin value and red and white cell counts should be sent with thin, even blood films on clean slides. Rinsing the slides in 95 per cent alcohol and drying, before making the smears, will add to the ease of making even films. Slides which are stained immediately are always better than those submitted unstained. Wright's stain and distilled water for dilution and washing will usually produce good results. Glenwood-Inglewood triple-distilled water, sold in gallon bottles by a Minneapolis concern, or parenteral flask water, are ideal.

While peripheral blood studies are indispensible in many cases, they are not always diagnostic of specific disease, and now some pathologists want bone marrow to prove or disprove a condition suspected from study of the peripheral blood. The diagnostic value of expert bone marrow examination in obscure anemias and in unexplained chronic febrile conditions is gradually being appreciated.

In his role of consultant, the pathologist is naturally in a position to supplement the education of every doctor. Most men in the field are willing to return microscopic sections of material studied to the referring physicians. Some doctors profess histology to be out of their sphere and do not consider their judgment or knowledge in this field sufficient to enable them to gain anything from a study of sections. With a good pathologic report at hand, however, this is not the case, and many will find the study of surgical sections a refreshing departure from the routine of clinical practice.

The press of time prevents the average doctor from putting the acid test to much of his clinical diagnosis, but here the pathologist can be of further service. Post-mortem technique is not difficult, and any doctor can learn it from the observation of a few dissections, followed by practice.

CLINICAL-PATHOLOGICAL CONFERENCES

KIMMELSTIEL-WILSON SYNDROME

A. J. HERTZOG, M.D., and W.D. HAYFORD, M.D.
Minneapolis, Minnesota

Dr. William Hayford: (A-46-2190). This forty-nine-year-old woman was first admitted to the Minneapolis General Hospital in 1932, complaining of having had diabetes mellitus for three years. Her blood pressure was 138/80. A urinalysis showed 4 plus sugar and was positive for acetone. The blood sugar at this time ranged between 190 and 240 mg. per cent. A glucose tolerance test showed a diabetic curve. She was discharged on 25 units of regular insulin daily. She was next seen in 1935. Her blood pressure was 136/90. Blood sugar was 240 mg. per cent. She had not taken insulin during the previous year for financial reasons. Her diabetes was controlled and she was discharged on 40 units of regular insulin daily. Her final admission was on August 15, 1946. She was complaining of swelling of the legs and abdomen for the past two years. Acute complaints were swelling of the upper extremities and eyelids, and nausea and vomiting. For the past few weeks she had blisters of the legs. When they broke, they drained for long periods of time. She was short of breath. The edema of the lower extremities gradually progressed upwards to involve the hips. In the last few months her abdomen had begun to swell. She required three pillows in order to sleep at night. She urinated four times a day and only small amounts.

On physical examination, the blood pressure was 190/92. The pulse was regular and 80 per minute. The patient was slightly dyspneic. There was edema of the eyelids. The breasts were distended with fluid. The tissues of the chest posteriorly pitted on pressure. Auscultation of the lungs demonstrated moist rales bilaterally in the lower lung fields. The respiratory rate was 32 per minute. Heart examination showed the point of maximal impulse to be 11 cm. to the left of the midsternal lines. There was a slight apical systolic murmur. There was marked ascites and grade 4 pitting edema of the lower extremities. There were small bullae on the lower legs, some of which had broken and were oozing fluid. There was two plus pitting edema of the upper extremities and three plus pitting edema of the sacral region.

Urinalysis showed a specific gravity of 1.034 with 3 plus albumin and occasional red and white blood cells. The urine sugar varied with the amount of insulin. Every urinalysis showed from 3 to 4 plus albumin with many red cells and pus cells. A quantitative albumin determination showed an excretion of 12 grams of albumin in a twenty-four-hour specimen. Blood urea nitrogen was 23 mg. per cent. Blood sugar was 140 mg. per cent. Plasma proteins varied from 6.7 to 6.5 grams per cent. Quantitative determinations of plasma proteins showed 3.93 grams of albumin and 2.73 grams of globulin. On August 23, 1946, her venous pressure was 21 cm. of citrate. The circulation time was 15 seconds. She was given mercurial diuretics and subsequently voided 7,675 c.c. of urine. Thoracentesis was done and several thousand cubic centimeters of fluid were removed from her chest. The hemoglobin, white blood count and differential blood count were within normal limits. The prothrombin level was normal. Serology was normal. Blood chlorides and carbon dioxide combining power were within normal range. The P.S.P. test for kidney function showed a total excretion of 35 per cent in two hours.

On September 22, 1946, the patient had a sharp nonradiating precordial pain and a pulse of 120 with a gallop rhythm. The symptoms were relieved by nitroglycerine. On September 27, the venous pressure was 25 cm. of citrate. The anasarca persisted. On November 5, 1946 while sitting on the side of her bed, she expired very suddenly.

Dr. Hertzog: Does anyone wish to explain the severe generalized edema that occurred in this diabetic woman?

Intern: Kimmelstiel-Wilson's syndrome.

Dr. Herman Koschnitzke: When a diabetic develops generalized edema with a marked albuminuria, we naturally think of Kimmelstiel-Wilson's syndrome. The plasma protein level in this case was not lower than 6.5 grams. She had hypertension and an enlarged heart. She had an attack of cardiac pain relieved by nitroglycerine. An electrocardiogram showed low voltage of the QRS complex, a slight ST depression, and tachycardia with a gallop rhythm. Her venous pressure was 25 cm. of citrate. Hence she definitely had heart failure. We thought that the edema, however, was out of proportion to the degree usually seen in heart failure. It is reasonable to believe that the lowered plasma protein may have been a contributing factor in her generalized anasarca.

Dr. Hertzog: Kimmelstiel and Wilson[3] called our attention to the so-called intracapillary glomerulosclerosis of the kidneys in diabetes mellitus. They emphasized a nephrotic syndrome associated with this renal lesion in diabetics. The Kimmelstiel-Wilson syndrome has been used very loosely to describe the edema

---

From the Department of Pathology, Minneapolis General Hospital, A. J. Hertzog, M.D., pathologist.

due to heart failure in diabetics. A restricted definition would be edema in a diabetic resulting from albuminuria and hypoproteinemia as a result of intracapillary glomerulosclerosis of the kidneys. Hypertension occurs because of the vascular changes in the kidneys. Most of the cases give a history of a normal blood pressure at one time. The hypertension as in this case is of gradual onset. Porter and Walker[4] describe the typical events of a case of Kimmelstiel-Wilson syndrome as shown by one of their cases. Diabetes mellitus was diagnosed in 1929 at the age of thirty years. In 1932, albuminuria, mild edema, and hypoproteinemia were first noticed. Blood pressure was 98/65. In 1937, edema was marked. The blood pressure had risen to 160/80. Albuminuria was 3 plus. Total plasma proteins were 4.1 grams per cent. In 1938, blood pressure was 180/95. Anasarca was marked. Renal insufficiency developed and she expired. Dr. Bell[2] has studied the kidneys of 606 diabetics at autopsy. He found the lesion of intracapillary glomerulosclerosis of both the nodular and diffuse type in 22 per cent of males and 36 per cent of females. One can diagnose about 20 per cent of cases of diabetics at autopsy from the microscopic findings in the kidneys alone. Allen[1] believes because of the high incidence and clear-cut character of the glomerular lesion in diabetics, the kidneys offer the most reliable histologic diagnosis of diabetes mellitus of the age group over forty years. We can diagnose about 50 per cent of diabetics from the changes in the islands of Langerhans with the usual hematoxylin and eosin stain. When the beta granules of the islands are studied with the Gomori stain, this percentage goes up considerably. In Dr. Bell's series only about one-third showed appreciable edema in spite of the renal lesion. The edema when present appeared to be due to heart failure rather than hypoproteinemia. Diabetics today die largely of complications related to cardiovascular disease rather than coma. The marked tendency of a diabetic to develop arteriosclerosis at an early age appears to be uninfluenced by insulin therapy. Dr. Hayford will give the autopsy findings.

Dr. William Hayford: The body was that of a middle-aged female, measuring 161 cm. and estimated to weigh 160 pounds. There was generalized anasarca present with marked pitting edema of the lower extremities. The abdominal cavity contained approximately 3,500 c.c. of straw colored fluid. Each pleural cavity contained approximately 800 c.c. of similar fluid. The heart weighed 440 grams. There was moderate hypertrophy and dilatation of both ventricles. There was a large fibrous scar resembling a healed infarct that involved the greater part of the left anterior ventricular wall. The coronary arteries showed grade 4 sclerosis with complete occlusion of the anterior descending branch of the left coronary. The cardiac valves appeared normal. The lungs showed moderate generalized edema and atelectasis as a result of the hydrothorax. The liver was enlarged and weighed 2,350 grams. It had the gross appearance of severe passive congestion. The pancreas appeared to be of normal size and consistency. The right kidney weighed 210 grams and the left 240 grams. Both kidneys were large, pale, and finely granular. The remaining organs showed nothing of note.

Dr. Julian Sether: The microscopic slides show passive congestion of lungs and liver. The lungs contain many macrophages filled with brown pigment as found in the so-called "heart failure" cells. The myocardium shows the picture of an old myocardial infarct with a large fibrous scar. The pancreas with a hematoxylin and eosin stain shows partial hyalinization of many islands. A Gomori stain shows marked reduction of the beta cells of the islands. It is estimated that the islands do not contain more than 10 per cent beta cells. Our interest is naturally centered on the kidneys. The afferent arterioles show marked subintimal hyalinization and thickening of the walls. The hyaline material extends from the arterioles into the glomerular capillaries to cause a marked intercapillary thickening. The hyaline material is deposited between the glomerular capillaries. Most of the glomeruli show this lesion to be diffusely distributed throughout the tuft. An occasional one shows the hyaline material to be localized and circumscribed in distribution. There are some areas of cortical atrophy present. The tubules show nothing of note.

Dr. Hayford: The anatomical diagnosis then is (1) diabetes mellitus, (2) intracapillary glomerulosclerosis of the kidneys, (3) hypertrophy and dilatation of the heart (hypertension), (4) coronary sclerosis with myocardial fibrosis, (5) passive congestion of liver and lungs, and (6) bilateral hydrothorax and ascites. We considered the edema to be due largely to heart failure. It is plausible to believe that the lowered plasma proteins may have been a contributing factor to her generalized anasarca. In reviewing the literature on Kimmelstiel-Wilson's syndrome, one is impressed by the lack of quantitative studies. Few cases record the plasma protein level and extent of heart failure. Many times the diagnosis was made on patients who were in a moribund state on admission to the hospital and without benefit of autopsy confirmation.

DIAGNOSTIC CASE STUDY

ARTHUR H. WELLS, M.D., OLIN W. ROWE, M.D., and HAROLD H. JOFFE, M.D.
Duluth, Minnesota

Dr. A. H. Wells: We have a most remarkable diagnostic problem of the dramatic and rapidly fatal type.

Dr. O. W. Rowe: I saw this fifteen-year-old school boy in his home about forty hours before his death and three days after he had developed abdominal distress, fatigue, and difficulty in breathing. These symptoms were first noted after the boy lifted a heavy boat anchor out of the river. They gradually increased in severity. He had been under my care since birth, and was in apparent excellent physical and mental health at the time of onset of his present illness. He was lying on his left side, a little cyanotic and breathing rapidly. He pointed to the mid upper third of the abdomen as the seat of pain. The lung excursions were equal. Heart sounds were faint. There were confused faint murmurs, one of which was systolic, apical, and apparently not transmitted. His pulse was 125 per minute, faint and regular. I was unable to get his blood pressure. The abdomen was soft and not tender. My immediate diagnosis was that of acute cardiac condition, possibly pericarditis with effusion.

At the time of admission to the hospital fifteen hours before death, the physical examination revealed a robust fifteen-year-old boy, measuring 67 inches and weighing about 160 pounds, in acute distress with dyspnea and cyanosis. He was very weak and tended to lie on his left side. Circulatory collapse was continuous. His pulse was 68, respirations 24, and rectal temperature 102.4° F. There was air-hunger type of respiration with limited but equal expansion of the lungs. The apical beat of the heart was not visible or palpable. The heart sounds were weak and distant. A diastolic apical murmur was heard on one examination. A doubtful pulsus paradoxus was noted and later pistol-shot sounds were heard over the femoral arteries. There was some tenderness in the epigastrium. Otherwise, the abdominal examination was entirely normal. His distress had become continuous and located much of the time in the lower thorax.

Two consultants, Dr. F. J. Hirschboeck and Dr. S M. White, could hear a pericardial friction rub the first day of his illness which disappeared later. Aspiration performed by Dr. M. G. Gillespie failed to produce any fluid from the pericardial sac. The consultants felt that the patient had a circulatory collapse of unknown etiology.

A portable film of the chest revealed no enlargement of the cardiac shadow or distortion of the shape of the heart. There was slight congestion in both lungs according to Dr. Arden L. Abrahams. Dr. S. H. Boyer, Sr., interpreted the electrocardiograms (Fig. 1) as follows: rapid rate and regular rhythm; ST_2, depressed, rises with slight concavity to pointed apex; T_3 inverted, T_4 upright, and T_{1-2-4} upright, do not exceed normal voltage. The diagnosis was that of auricular tachycardia, T_3 inversion. In the absence of other signs and characteristic features of posterior infarction, such inversion is normal to childhood and even in youth may be accepted as of no significance unless later records disprove this. ST_2 depression is sometimes seen in pericarditis. There was a white blood count of 17,500 with 57 per cent neutrophils, 41 per cent lymphocytes and 2 per cent monocytes.

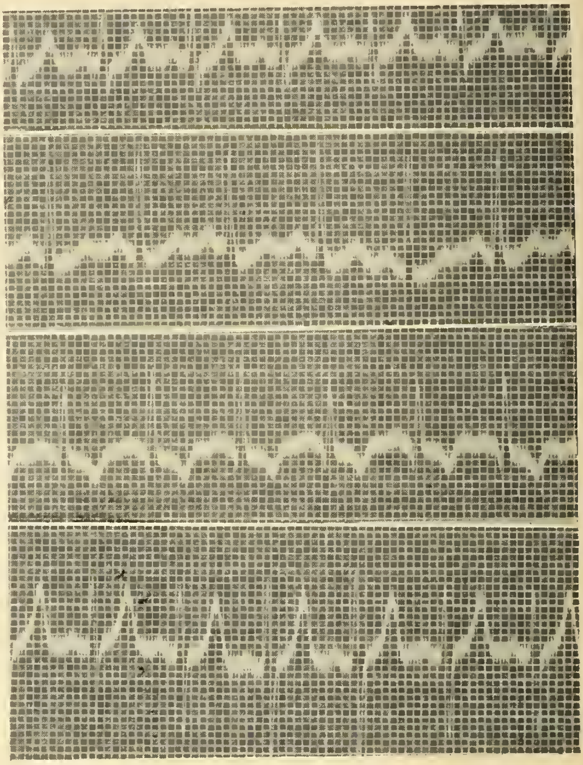

Fig. 1. Electrocardiograms leads 1, 2, 3, and 4 in order.

He was kept on absolute bedrest with nasal oxygen to 6 liters, coramine 2 c.c. every three hours, light diet, fluids not to exceed 2,000 c.c., and one hypodermic injection of morphine, grains 1/8. He continued to complain of abdominal and lower thoracic distress. He was constantly cyanotic and his weakness was progressive and severe. He vomited small amounts of bile stained fluid twice during his last fifteen hours. During the last nine hours his body was cold and clammy. His blood pressure and pulse rate were unobtainable. Respirations increased to 40, and the temperature reached 105° F. He became restless and irrational during the last two hours.

From the Department of Pathology, St. Luke's Hospital, Duluth, Minnesota. Clerical Assistance by Miss Faith A. Gugler.

Dr. A. H. Wells: The case is open for diagnosis.

Physicians: Acute pericarditis, acute rheumatic pancarditis, Fiedler's myocarditis, coronary thrombosis, acute endocarditis with ruptured bicuspid aortic valve, acute cor pulmonale of unknown origin.

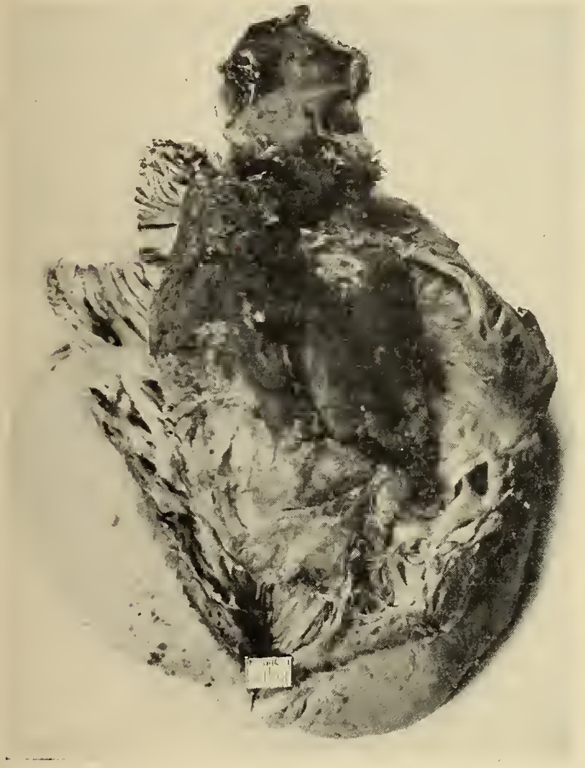

Fig. 2. The rhabdomyosarcoma almost filling the right auricle and ventricle.

Necropsy

Dr. A. H. Wells: The post-mortem examination revealed a large, hemorrhagic, friable, pedunculated tumor mass (Fig. 2) measuring 12 cm. long and 6 cm. in diameter at its largest dimensions. It hung from a site of attachment 2.5 cm. in diameter directly overlying the usual site of the foramen ovale in the right auricle. The mass filled the tricuspid orifice and extended into and almost filled the right ventricle. There was not more than a 3 mm. extension into the interauricular wall. The cardiac cavities, valves, vessels, pericardium, and myocardium were otherwise entirely normal. The heart weighed 360 grams. There was no evidence of chronic passive congestion, edema, metastases, congenital anomalies or significant change in other organs. The brain was not examined.

Microscopic.—Possibly 95 per cent of the cardiac tumor mass was necrotic and hemorrhagic. A few preserved areas were composed of a moderately cellular, highly anaplastic lesion, characterized by a predominance of long spindle-shaped cells, with occasional larger multinucleated, rounded, or elongated cells. A finely granular cytoplasm frequently contained longitudinal and cross striations (Fig. 3). The nuclei tended to be oval or elongated and had a hyperchromatic granular chromatin which on occasions appeared in ill-defined linear arrangements. No "spider cells" of congenital rhabdomyoma could be found.

In conclusion, this otherwise normal fifteen-year-old boy died as the result of tricuspid block caused by a pedunculated rhabdomyosarcoma of the right interauricular septum.

Discussion

In spite of the rarity of primary tumors of the heart, the subject has been reviewed[3,6,14] repeatedly, so that many facts concerning these lesions are well organized and the controversial subjects clearly defined. The exact frequency of these neoplasms has not been determined at present since as many as 30,000 autopsies have been performed[13] without finding a single case. In other instances, 8,550 necropsies produced four primary tumors,[10] 1,200 examinations revealed three cases,[12] and in our hospital one case was found in the last 3,000 autopsies. By 1945[13] primary heart tumors totaling 163 had been counted in the literature. There were sixty-three "authentic" cases[2] of rhabdomyoma and apparently only four cases[7,8,9] of rhabdomyosarcoma of the heart.

The primary tumors of the heart can be readily classified into five groups: myxoma, fibroma, rhabdomyoma, sarcoma, and rare miscellaneous tumors. The malignant varieties represent 29 per cent of the total.[8]

Pathology

The myxoma is the most frequent of the primary cardiac tumors. Its benign, frequently pedunculated nature, its usual site of attachment on the left interauricular septum, and its occasional mitral stenotic clinical syndrome, sometimes altered by the position of the patient, make it the one heart tumor which might be recognized and cured by operation. The exact nature of this lesion has been debated. Some feel that it is not a true neoplasm but a myxomatous change in an edematous thrombus. The majority favor its neoplastic nature. A poorly cellular, edematous, Wharton's jelly type of tissue bespeaks a slow-growing benign character.

Small, rounded or papillary, generally pedunculated tumors composed of adult fibroblasts form the second most common group of heart tumors (fibromas). These have been found attached to some one of the heart valves. They have been innocuous and consequently innocent pathologic curiosities.

The benign rhabdomyomas are undoubtedly the most intriguing of the cardiac tumors. Over half of the cases occur in the first year of life, and only seven cases have been described in patients over fifteen years of age.[2] In 50 per cent of the patients with this lesion, there is an associated tuberous sclerosis of the brain.[8] One is also very likely to find other congenital anomalies, including cleft palate, harelip, cystic kidneys, multiple gliomas, hypernephroma, sebaceous gland adenomas, embryonic rests in the kidney and malformations of the pancreas. These frequently associated dysontogenetic lesions are a strong argument in favoring the common opinion that rhabdomyomas of the heart are not true neoplasms but hematomas. They are described in three gross forms[2]: single nodules usually near the apex; multiple nodules scattered through the heart; and, rarely, diffuse involvement of the myocardium even to the point of complete replacement. The cells composing these nodules are tubular and similar to those found in the embryonic heart muscle of the thirteenth week of fetal life.[5] Their large glycogen content results in a typical "spider-cell" appearance. When cut at a right angle to the length of the cell, strands of cytoplasm suspend the centrally placed nucleus to the thick outer wall. The cytoplasm may have cross striations. The hollow spaces contain glycogen.[2]

Only one nonconvincing case of malignant transformation of a rhabdomyoma to a rhabdomyosarcoma has been described.[8] It is entirely possible that rhabdomyosarcomas of the heart are a separate oncologic entity. The finding of typical multiple rhabdomyomas, tuberous sclerosis or other commonly associated lesions in a patient with a rhabdomyosarcoma seems essential before relating the two conditions.

It is entirely possible that the last relatively large group of primary cardiac neoplasms, the sarcomas, may contain instances of rhabdomyosarcoma without the necessary identifying striations. The majority of the sarcomas described[14] are simply designated as round cell, spindle cell, giant cell, or myxosarcoma. They occur at any age. They generally arise in the auricles, especially on the right side, and often from the interauricular septum. Occasional metastases to other organs are recorded. At times they become huge before causing death.

Secondary tumors of the heart are more frequent than the primary neoplasms, occurring in approximately 7.3 per cent of all deaths due to malignancy.[11] They are metastatic from practically all sites of carcinomas, sarcomas, melanomas, and the leukemias. The origins of greatest frequency are the bronchogenic and breast carcinomas.[11] However, the incidence of heart involvement in melanomas, reticulum cell sarcomas, and leukemias may be over 50 per cent. They are found in any part of the heart. Possibly because of the great preponderance (three fourths) of cardiac venous return through the Thebesian venae minimae into the right ventricle (Kretz) most of the metastases are found in its walls. It has become obvious through the years of post-mortem examinations that those malignancies which invade the heart usually are not inhibited by the other tissues seldom involved by metastases, such as the spleen, pancreas, thyroid, and voluntary muscle. They generally have a very wide distribution of metastasis and are quite embryonic in type. This obvious immunity of specific tissues to metastases could be the clue leading to the discovery of an efficacious therapeutic extract for the control of cancer.

Clinical Recognition

Primary or secondary heart tumors cause cardiac embarrassment by (1) mechanically blocking of a valve (mitral and tricuspid), (2) interference with transmission of the electrical impulse, (3) pericardial effusion, and (4) extensive destruction of myocardium by infiltration. These various lesions can give rise to almost any sign or symptom of heart disease. However, there are certain manifestations or cirumstances which have aided in the recognition of neoplasms in the heart.[9,14] The ball valve action of a tumor may cause a murmur which changes or disappears with change of position and the effect of gravity on the tumor mass. The electrocardiogram[1] may demonstrate a heart block or bundle branch block which cannot be easily explained because of lack of the other signs pointing to coronary disease. The pericardial effusion is frequently hemorrhagic and occasionally contains demonstrable neoplastic cells. Malignancies of the heart causing cardiac embarrassment are generally large and at times cause distortion of the shape and size as best demonstrated by roentgenologic methods. What intravenous radio-opaque dyes can do in demonstrating these lesions needs further elucidation. In any patient with known malignancy, the sudden onset for cardiac symptoms may well be on the basis of cardiac metastasis. Intractable myocardial insufficiency without obvious cause may be on a tumor basis.[9,14]

Although very few tumors of the heart have been recognized as such prior to necropsy, the time should come when a benign pedunculated myxoma of the left interauricular septum will be clinically recognized and surgically cured. More alert physicians are already metastatic-cardiac-tumor conscious.

Summary

1. A fifteen-year-old boy developed abdominal and thoracic distress, muscular weakness, and dyspnea, progressing to circulatory collapse and death over a five-day period.
2. Necropsy revealed a rhabdomyosarcoma of the right interauricular septum with much necrosis and recent hemorrhage which had blocked the tricuspid valve.
3. This appears to be the fifth rhabdomyosarcoma of the heart in the world literature.
4. A very brief review of the more important facts and theories concerning both primary and secondary neoplasms of the heart is recorded.

HISTORY OF THE CIRCULATION

(Continued from Page 267)

that they exist. It must be recalled that Cesalpino also suggested that an anastomosis existed between the arteries and veins. Harvey further explained that both the arteries and the veins contain blood and that movement of the blood is progressive, not undulating. He also showed that the functional center of the cardiovascular system is the heart, not the liver.

In this rather brief review of the history of the discovery of the circulation of the blood, facts have been recorded as they are found in the annals of history. After these many centuries the primary concern is no longer with priority of discoverers but rather with the importance of observations and conclusions as recorded by the contributors. History unmistakably inscribes the chronology of events. Each is important and its individual merit should be emphasized as we today contemplate in retrospect on the progress of history and the influence of these various contributions on what is known at this time as modern medicine.

CASE REPORT

ADENOCARCINOMA OF THE SWEAT GLANDS WITH METASTASES

A. E. BENJAMIN, M.D.

Minneapolis, Minnesota

MALIGNANT tumors of the sweat glands with metastases are rare. Gates, Warren and Warvi[1] reported thirty-five cases, four of them with metastases. The case I wish to report is one of interest because of the many areas and tissues involved and the associated lesions present.

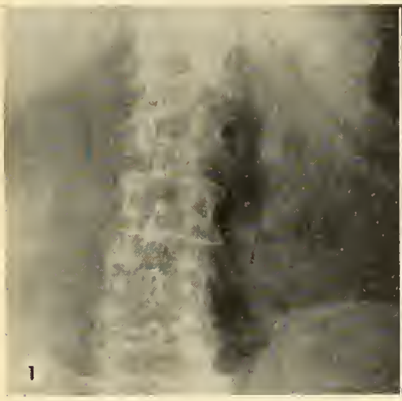

Fig. 1. X-ray of the abdomen on August 11, 1943, before operation. The density in the right abdomen suggests a soft tissue mass. The operative findings showed that this was probably secondary to an intra-abdominal hemorrhage from a lesion in the liver.

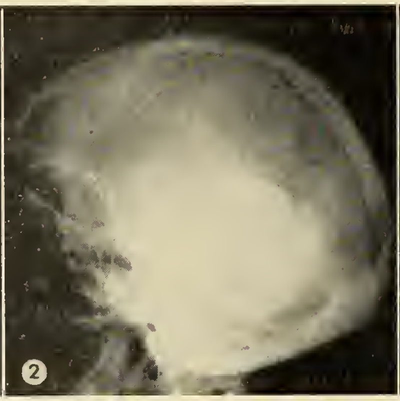

Fig. 2. Lateral view of the skull. The shadow of a dense tissue mass may be seen about the right ear, with erosion of the temporal bone about the mastoid and eburnation which was probably secondary to an infection in the tumor mass. Several nodules in the scalp could be seen in the original film but are lost in reproduction.

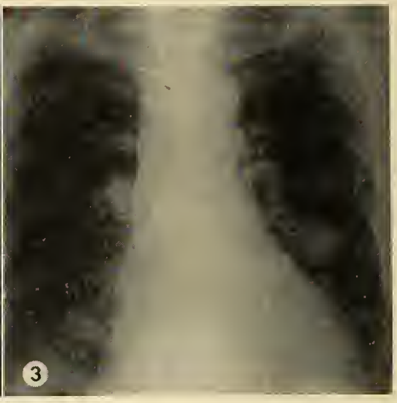

Fig. 3. X-ray of the chest on April 29, 1946, shows multiple rounded densities in the left lung which are most probably carcinomatous metastases.

Case Report

Mrs. C., aged 76, a widow for twenty years, was of Irish descent. She had had the ordinary diseases of childhood. Her tonsils had been removed in her earlier years. Twenty years ago, she noticed a skin tumor in front of the right ear. In two years time, this grew quite large, and she had it removed. Apparently it was malignant, for she had radium and x-ray treatments following the operation. Her father died of cancer of the mouth at seventy-nine years of age. Her mother died at twenty-four following childbirth. Mrs. C. was married at eighteen and at the time of examination had three grown children, all healthy. Another child, a daughter, died several years ago of tuberculosis. Her husband died of cancer of the mouth twenty years ago. Her menopause, when she was fifty, arrived with no particular disturbances.

When first seen by me in August, 1943, she complained of pain in the upper right quadrant. This pain had started one month previously. Her general health had been quite good. Her weight was 120 pounds; she was 5 feet 5 inches tall. She had worn glasses for about eight years. She stated she became somewhat deaf in her right ear fifteen years before, followed shortly by bilateral, nearly total deafness. She had been wearing a hearing aid since.

She had quite a large growth involving the external right ear and mastoid area, one involving the skin of the right breast, several growths on the scalp, and some on the arms, legs, and back, ranging in size from 1 to 5 cm. in diameter. These were dark in color and raised above the skin. She had upper and lower plates. Her mouth and throat seemed healthy. There was no thyroid disturbance. She had no cough or bronchial trouble. Her heart was normal. Her blood pressure was 140/72. There was no lymphatic enlargement. The liver was enlarged, the lower border extending 1.5 inches below the costal margin. There was pain upon percussion over the gall-bladder area and dullness over the upper right quadrant and some over the whole abdomen. She had a second degree prolapse of the uterus with a marked cystocele. She had no hernia. The bones and joints seemed normal. Her reflexes were normal. She had some varicose veins of the lower extremities. Her hemoglobin was 64 per cent. The urine contained a trace of albumin. Her bleeding time was 1 minute, 10 seconds; clotting time was 4 minutes. The blood Wassermann test was negative. Her temperature was 100; pulse, 78; white cell count, 11,800; and red cell count, 2,970,000.

The growths were thought to be malignant.

Read at the annual meeting of the Southern Minnesota Medical Association, Faribault, Minnesota, September 9, 1946.

Because of the severe pain in the upper right quadrant, a flat plate was taken, and a shadow in the vicinity of the gall bladder was noticed (Fig. 1). On August 12, 1943, three tumors were removed from the right lower leg, one from the right breast, and one from the forehead for biopsy. These involved the skin alone. The pathologist reported adenocarcinoma of the sweat gland type.

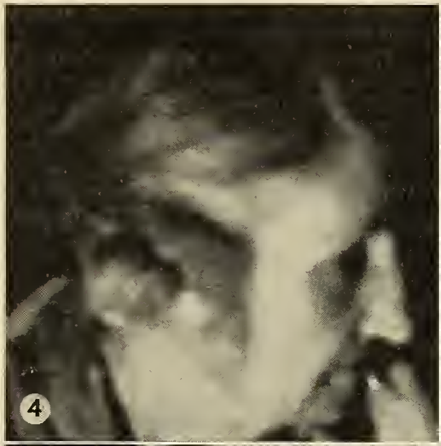

Fig. 4. Tumor of the right ear before operation.

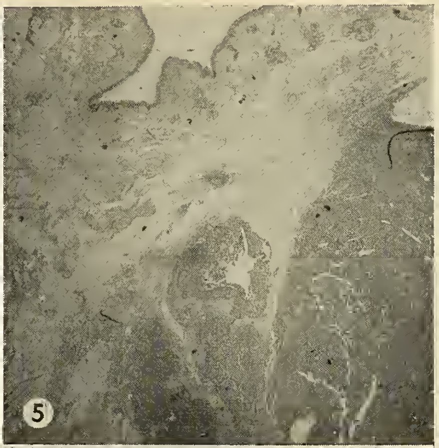

Fig. 5. Photomicroscopic section of the right ear shows malignant degeneration of a cylindroma involving the ear.

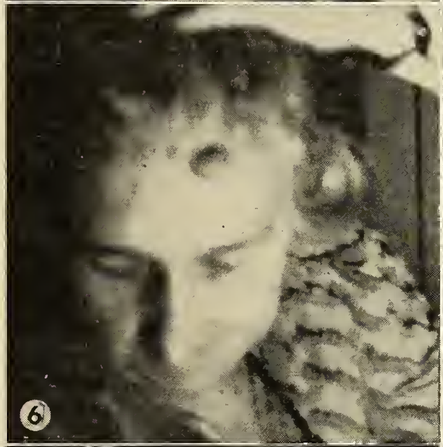

Fig. 6. Malignant growth of the scalp and forehead before operation.

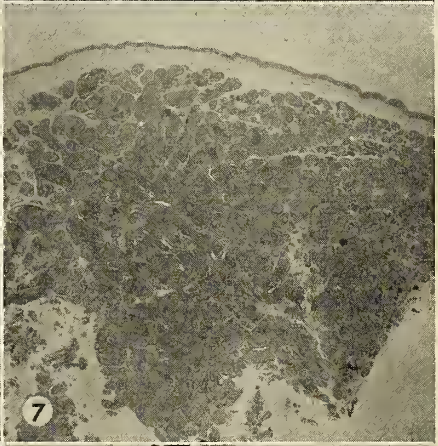

Fig. 7. Photomicroscopic section of a scalp cylindroma (turban tumor).

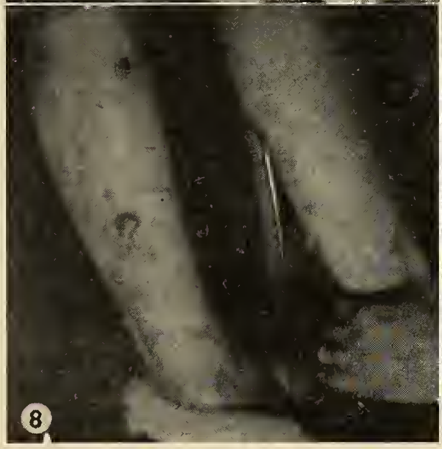

Fig. 8. Malignant growths on the legs before operation.

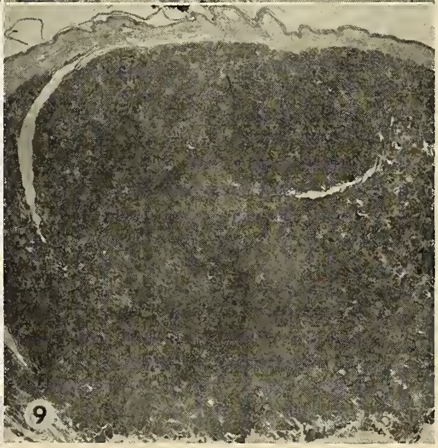

Fig. 9. Photomicroscopic section of a skin cylindroma with characteristic cytology.

Because of the continuous pain in the right upper quadrant and the possibility of a stone in the gall bladder, an exploratory operation was performed on August 17, 1943, through the outer border of the right rectus. The muscle was retracted and the peritoneum opened back of the muscle. The abdominal cavity contained a great deal of blood from a hemorrhage that apparently had occurred from the under surface of the liver, where there were a few greyish nodules. The omentum was adherent to the nodules and liver. The upper surface of the liver was smooth and the right lobe was enlarged. The organ was congested and inflamed. The gall bladder and other abdominal organs were apparently normal, and no stone was found. The adhesions were separated and a portion of the border of the liver including a nodule was removed for biopsy. This was thought by the pathologist to be malignant, but the specimen was reviewed by Dr. E. T. Bell and others who believed it to be an angioma. A positive diagnosis was not made.

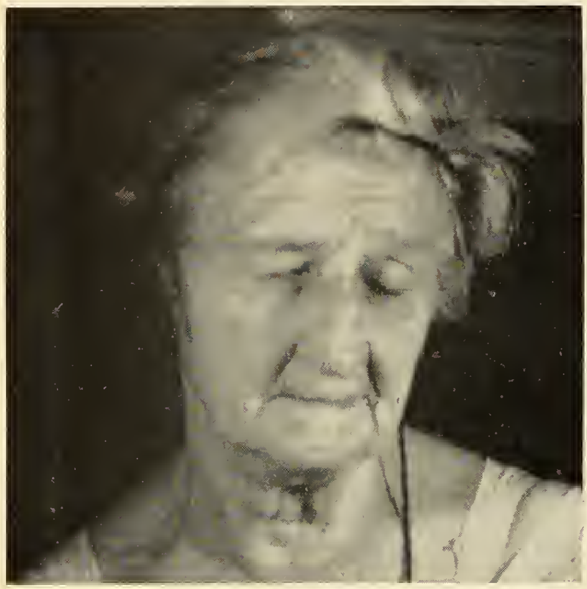

Fig. 10. The patient after removal of the growth of the external right ear and the growths on her forehead and scalp.

Transfusions were given following the operations. The patient made satisfactory progress. The bloody drainage gradually ceased and she was allowed to get up in a few days.

The patient did not require any special attention until April 22, 1946, when she returned complaining of pelvic distress and bleeding from the ear. She was weak and her hemoglobin was 40 per cent. The uterus was prolapsed and a cystocele was present. She had no growth or signs of malignancy in the pelvis. Appropriate diet and blood building remedies were employed. A pessary to support the bladder and uterus was fitted. The bleeding surface of the ear was treated. On April 29, 1946, x-rays were taken of the skull (Fig. 2) and lungs (Fig. 3). These showed invasion of the mastoid and possibly cancer of the lungs.

Because of the large and bleeding tumor of the ear (Fig. 4) which she had previously refused to have removed, we operated on May 2, 1946, removing all of the external ear and the contiguous tissue involved. The skull was not interfered with except to cauterize it, as we removed the malignant tissue by means of the electric knife. The pathologic report was basal cell carcinoma (Fig. 5).

Her progress was very satisfactory, and inasmuch as she seemed to improve after these various procedures, she and her family were anxious to have all remaining growths marring her appearance removed (Fig. 6). We then, on May 10, removed, under local anesthesia, three growths from the frontal region, one from between the shoulder blades, one from the left shoulder, and one from the lumbosacral region. The pathologist reported these growths to be basal cell carcinoma (Figs. 7 and 9).

There still remained the following smaller tumors; five growths on the lower left leg, seven on the right leg (Fig. 8), three more on the back, two on the scalp, and two on the upper right thigh. These we removed under local anesthesia five days later.

The wounds all healed perfectly (Fig. 10), and the patient seemed happy and well satisfied. There remained a little drooping of her right upper eyelid because of a nerve and muscle injury from the operation. The denuded area where the external ear was removed has now healed over, and she covers the defect with a lock of hair.

There remains, however, at this time, within the external auditory canal a small granular mass which probably is malignant, but which we will remove soon with the electric needle.

She weighs 126 pounds. Her hemoglobin remains about 70 per cent. Her general health is good, and she gets about alone.

Comment

This case is of particular interest because of the numerous growths and metastases which have occurred since she first noticed the tumor in front of her right ear twenty years ago. This tumor may have been the same malignant type of the sweat glands. There was no recurrence until a number of years later when it developed in the same location with involvement of the ear and skull, a tumor in the liver with hemorrhages, probable malignant growths in the lungs, and numerous malignant growths of the sweat glands of the scalp and skin of the body and extremities, these tumors being considered similar in nature by the pathologists. It is interesting to note that she has made improvement in a general way since all of these growths have been removed.

NOTES ON THE HISTORY OF MEDICINE IN FILLMORE COUNTY PRIOR TO 1900

By NORA H. GUTHREY
Mayo Clinic
Rochester, Minnesota

(Continued from February issue)

A **Dr. Keller** settled in Preston around 1882 and for a few years practiced medicine and surgery there. It has been recalled by the daughter of an early settler, Mr. Joseph Pickett, of Carimona, that in her father's last illness one of her two physician uncles (Dr. William C. Pickett, founder of Carimona, and Dr. Horace W. Pickett) called Dr. Keller in consultation, and that Dr. Keller finally took the case alone.

Dr. Keller, although he possessed the confidence of many persons of judgment, physicians and laity, who believed him to be a skilled member of the medical profession, incurred the disfavor of others, as witness the following broadsides, the first of which appeared in the local *National Republican* in August, 1883:

> Quacks thrive by appropriating as their own the skill and knowledge of others. Dr. Love is one of the sufferers by this too common practice. The sap-head reporter of the *Lanesboro Journal* is doing what he can to give credit for service to others than those who perform it. When either Dr. Love or Dr. Knowles has an accouchement case, he hastens to report that Dr. Keller was the professional attendant. There are several such cases which exhibit the retailer of lies as a scavenger worthy of the dirt he consumes.

And the second appeared in November, 1883:

> Dr. Keller, the quack, who deluded so many Prestonians into the belief that he was an accomplished physician, and who left last fall to "follow his profession in Texas," is in Chicago trying to get a diploma from the Homeopathic Medical College. Will that relieve him from the necessity of borrowing some other physician's small hand?

A Dr. F. Keller practiced in Red Wing, Goodhue County, for a few years, perhaps more, in the seventies. There is official record, which should be considered with the foregoing paragraphs, that on April 24, 1884, Dr. Francis Keller, once of Goodhue County but "now Fillmore, as per certificate," a graduate from the Medical Department of the State University of Iowa, early in 1884, was licensed by the Medical Examining Board of the State of Minnesota to pursue the practice of medicine in the state, and that on March 2, 1885, he formally filed his license with the clerk of the District Court of Fillmore County, as required by law.

Ambitious to extend his scope of practice in a larger place, Dr. Keller left Preston in the eighties, and some years later word came back to the village that he had built up a large practice in Los Angeles.

Herbert Kendall, a graduate of Rush Medical College, was practicing medicine in Spring Valley in 1880, and in that year, at the annual meeting of the Minnesota State Medical Society which was held at Albert Lea on June 15, he was elected to membership in the association. Other mention of him has not been found.

William Nassau Kendrick was born at Athens, Leeds County, Ontario, Canada, on June 15, 1872, the son of Samuel Kendrick and Amelia McNish Kendrick, both of English parentage and natives of Oak Leaf, Ontario. Samuel Kendrick lived until 1903, his wife five years longer.

William Kendrick went to school in Athens, and subsequently was a student at the Almonte Collegiate Institute, at Almonte, Canada, from which he was graduated with honors in 1890, at the age of seventeen. Two years later, having decided to become a physician, he entered McGill University, from which he was graduated in 1896, again an honor student and the president of his class, with the degree of M.D. C.M.; among the awards for scholarship which he had received during his course of four years were the Primary Prize, the Prize for General Proficiency, and the Gold Medal for Proficiency in Chemistry.

Immediately after taking his degree in medicine, Dr. Kendrick came to Spring Valley, Minnesota, to join his half-brother, Dr. J. Ross Johnson, in practice, and on June 9, 1896, was licensed as a physician in the state. In Spring Valley, on October 14, 1896, he was married to Maud M. Lloyd, daughter of L. M. Lloyd of that place. In 1898 a second half-brother, Dr. Charles H. Johnson, of Austin, in neighboring Mower County, who was in ill health, persuaded Dr. Kendrick to become his partner; the association continued for eight years. During the period in Austin there were born to Dr. and Mrs. Kendrick two children, Dorothy Gertrude, on December 8, 1899, and William Lloyd, on March 16, 1903.

In 1905, after the death of his half-brother, Dr. J. Ross Johnson, Dr. Kendrick returned with his family to Spring Valley, where he spent the remaining thirty-one years of his life, a loved physician, high in the esteem and confidence of his patients and fellow townsmen. Among his professional contemporaries in the village were Dr. John D. Utley, Dr. Cyrus B. Eby and Dr. Eubert V. Simons, as well as others who were there for varying periods of time. These men and their fellow practitioners, in the late nineties and well after the turn of the century, experienced many of the difficulties and inconveniences that their earliest predecessors in medical practice had met; the scientific advances of the last two decades were then only visions in the minds of a few research workers.

Always a student, Dr. Kendrick did much postgraduate work, visiting clinics and hospitals, and twice taking courses at the Medical School of Northwestern University. He was a general practitioner, with special interest in diseases of the eye, ear, nose and throat, and he became well qualified in treatment for these disorders. An expert optician as well as an oculist, he fitted glasses for many of his patients. Dr. Kendrick early began to write occasional original articles for the medical journals, of which one of the first was a note on postpartum hemorrhage that was published in the *Northwestern Lancet* in 1898. He served on the local board of health and was a member of the local county medical society, the Minnesota Valley Medical Association, and the Southern Minnesota Medical Association (as stated previously, these two joined in 1911), and the state and the national medical associations.

Dr. Kendrick is recalled as a leader in every movement that had to do with the betterment of his community. He was a member of the Spring Valley Commercial Club, the Automobile Club, and the American Legion and of the following fraternal orders: the Masons (A. F. and A. M.; Grand Master of Minnesota in 1918); the Ancient Order of United Workmen, the Benevolent and Protective Order of Elks, the Modern Woodmen of America and the Modern Brotherhood of America. He was a Republican in politics, an Episcopalian in religious affiliation. During World War I he was an examiner of army recruits, local chairman of the Liberty Loan and Victory Drives, and he aided the national department of justice in locating hidden grain and in dealing with aliens. In October, 1918, he entered military service and was stationed at Camp Pike, Arkansas, until his honorable discharge on December 23, 1918. His favorite diversions, when time permitted, were hunting, fishing and golf.

Although Dr. Kendrick never fully recovered his health after an operation for ruptured appendix in 1912, and although he became the victim of agranulocytic angina, he continued in medical practice until his death, at Rochester, Minnesota, on January 21, 1936. He was survived by his wife, a son and a daughter, and a sister, Mrs. William McNaughton, of Ottawa, Canada. Three years later Mrs. Kendrick removed from Spring Valley to Brainerd where, until she died, on September 28, 1944, at the age of seventy-two years, she made her home with her daughter, Dorothy Gertrude (Mrs. E. C.) Parsons. Late in 1944 there were living of Dr. Kendrick's family, Mrs. Parsons, William Lloyd Kendrick, his son, a mining engineer at Coleraine, and three grandchildren.

Dr. Kendrick lives in the memory of all who knew him, distinguished for his professional ability and his personal integrity and worth.

Elling P. Kierland, who was born at Kjerland Homestead, Hardanger, Norway, on February 18, 1818, was educated in his native place, receiving his general grounding in the schools and his special training, in pharmacy and medicine, under a preceptor. As many another member of his family had done before him, he became a druggist and, although not a graduate of a medical school, a competent practitioner of medicine.

In 1839 Elling Kierland was married to Madli Hovlen, also a native of Hardanger, a religious, conscientious woman who was a fine wife and thrifty homemaker and a devoted mother to the seven children of the marriage. Dr. and Mrs. Kierland in 1856 came with their family to America, settling first on a farm in Winneshiek County, Iowa. After five years in Iowa they moved to Rushford, Minnesota, where Dr. Kierland operated a drug store with his sons, Thomas and Peter E. Kierland, the latter of whom subsequently became a physician in Rushford, a graduate of Rush Medical College in 1869.

In 1877 Dr. E. P. Kierland temporarily discontinued his practice of medicine to enter the hardware business with his son Louis in Canton, South Dakota, but on giving up this enterprise after a few years, he returned to Rushford where he resumed his preferred occupation. Not a graduate of a medical school, as has been stated, he had received excellent training and had improved his knowledge by study, as evidenced by his successful practice, so that on December 31, 1883, under the Medical Practice Act of that year, he received exemption certificate No. 733-3. Until the time of his death at the venerable age of ninety-four years he continued his work of caring for the sick.

Kind, generous, charitable, actively interested in the Lutheran Church and in civic affairs, Dr. Kierland was one of Rushford's most influential and upright citizens. He died on April 26, 1912, at Rushford, survived by three of his children, twelve grandchildren and ten great grandchildren. His family in 1943 was represented in the medical profession by three members: his grandsons, Dr. Peter Ernest Kierland (son of Thomas Kierland), of Alexandria, Minnesota, who for ten years was a physician of Harmony, Fillmore County, and Dr. George E. Hourn, of St. Louis, Missouri (son of Martha Kierland Hourn); and his great grandson, Dr. Robert Richard Kierland (son of Dr. Peter E. Kierland), of Rochester, Minnesota, since the entrance of the United States into World War II absent on military service. (Dr. Kierland returned to Rochester, where he is on the staff of the Mayo Clinic, in December, 1945.)

Peter E. Kierland, one of the seven children of Elling P. Kierland, pharmacist and medical practitioner, and Madli Hovlen Kierland, natives of Hardanger, Norway, was born in Hardanger in 1846 and when he was ten years old came with his parents and his brothers and sisters to America, to a farm home about ten miles east of Decorah, Iowa. Here in the country schools his education was continued. Early in the sixties the family moved to Rushford, Minnesota, where the boy, then fifteen, went to school and helped in the drug store which was operated by his father and his brother Thomas. Peter learned pharmacy from his father and, from 1862 to 1868, whenever time afforded, studied medicine under Dr. Billington, of Decorah, Iowa. At the end of that period he entered Rush Medical College, in Chicago, and from it was graduated on February 3, 1869, with honorable mention for high scholastic rating and with the degree of doctor of medicine.

The young physician, who is remembered as of medium build, with black hair and gray eyes, returned to Rushford to begin his professional life in the community in which the senior practicing physicians were his father, Dr. Thomas H. Everts and Dr. Henry C. Grover, and in which Dr. H. W. Eldred was a highly respected surgeon-dentist. Dr. Kierland was a Mason, a member of the Lutheran Church and from the first a useful citizen.

In Chicago Peter E. Kierland was married to Louise Anderson, and on his return to Rushford brought his wife home with him. Although she never had lived outside of a city, Mrs. Kierland entered fully into the life of the community and sought to share the hardships of a country doctor's routine, accompanying her husband in horse-drawn vehicles on many of his rural calls, regardless of weather. On one of these occasions, in the winter, when Dr. Kierland was to perform a surgical operation, a partial resection of the maxilla, the horse ran away and the cutter tipped over, spilling passengers, instruments and equipment in the snow. With neither his wife nor himself hurt, Dr. Kierland gathered up the paraphernalia and in due time carried out successfully the planned surgical procedure, which was followed by recovery of the patient.

In the second year of his practice, Dr. Kierland, whose fine intellect and scientific ability gave promise of great service to his community and to his profession, was stricken with pulmonary tuberculosis. In the hope that the journey and change of climate would prove beneficial, his father in 1870 took him to Norway but not long after their return to Rushford the young physician died, on January 28, 1871. His death was announced in the *Journal of* *the American Medical Association*: "He will not miss the haven of hope, with God at the helm."

Dr. Kierland was survived by his wife; their daughter and only child, Ella; his brothers, Thomas and Louis; and his sisters, Isabel Kierland Eide and Martha Kierland Hourn. Of that group, there were living in the early nineteen-forties only his daughter, Ella Dahl Kierland Rich, retired at Santa Monica, California, after a distinguished career as a concert pianist, and his brother, Thomas Kierland, ninety-two years of age (1943), who had retired some time previously after fifty-six years as a practicing pharmacist in Rushford.

E. J. Kingsbury, who was to become a well-known medical practitioner of southern Minnesota, was a native of New York State, born in Franklin County on August 23, 1832. When he was four years old the family moved to St. Lawrence County, where he grew up. He obtained his preliminary and academic education at a district school in Potsdam, at a select school in Raymondville and during six terms at the Raymondville Academy under Professor Montague. Thus prepared, at the age of eighteen years he began to study medicine under preceptors, the first instructor Herman A. Boland, of Raymondville, and the second, Dr. Goodrich, of Potsdam. He completed his medical training by attending lectures at the American Medical Institute at Cincinnati and he was graduated from that institution on March 14, 1854. Beginning his medical practice immediately in Oswego County, New York, he remained there until the autumn of 1855, when he traveled west to Minnesota Territory and settled in Mower County, pre-empting the southwest quarter of section 20, town 102, range 14, in the present Bennington Township. In fact, he assisted in the organization of the township and served as first chairman of the first board of supervisors. After a few years he moved, in the autumn of 1860, to the village of Spring Valley, in Fillmore County, where he remained in active medical practice for eight years. During this period there was occasional mention in county records of his having received fees for medical attendance on paupers.

In Spring Valley, if not immediately on his arrival, at least prior to 1865, he had his offices on Broadway, opposite the tinshop. A professional card in the *Preston Republican* of March 10, 1865, announced that E. J. Kingsbury and Brother—the first and only mention found of the brother—were physicians and surgeons, and a postscript set forth the following information:

> E. J. Kingsbury, having been appointed Examining Pension Surgeon by the Commissioner of Pensions, will attend to all applications for pensions with promptness and dispatch. They will also attend to the collection of back pay and Bounty.
>
> E. J. Kingsbury
> W. B. Kingsbury

Late in 1868 Dr. E. J. Kingsbury moved to Decorah, Iowa, where he remained until 1870, when he again settled in Mower County, in the village of LeRoy, which became his permanent home. The beginning of his practice there was coincident with an outbreak of diphtheria during which he served faithfully and with such success as to establish him in the confidence of the community. During his first year in Le Roy, Dr. Kingsbury was one of several reputable physicians of Iowa and Minnesota to endorse, in a notice in *Western Progress*, the newspaper of Spring Valley, one Dr. H. J. Stalker, mentioned earlier, apparently a dentist of merit who traveled about the region.

E. J. Kingsbury was married twice, the first time on July 3, 1853, to Lucia A. Angell, who was born at Pomfret, Vermont, on April 8, 1829. Mrs. Kingsbury died in Spring Valley, Minnesota, on September 28, 1867, leaving one child, Flora A. Kingsbury; an infant son had died a year earlier. Dr. Kingsbury's second marriage took place on October 21, 1868, to Mary G. Hard, who was born in Broome County, New York, on September 21, 1846. Of this marriage there were three children, Mattie J., Mildred A. and Elmer J. Kingsbury.

A strong advocate of temperance, E. J. Kingsbury from the age of seventeen years was a member of one temperance organization or another. That he was a man of active intellect and professional versatility was evidenced by the fact that he studied law and became a qualified member of the bar of Minnesota, admitted on April 6, 1882, to practice law in all courts in the state. In 1884 he had been serving for four years as police justice of Le Roy.

Dr. Kingsbury is said to have died in 1885, at the age of fifty-three years.

S. H. Knowles for a time in the early eighties was in Preston, Fillmore County, and in this period, on July 25, 1883, aged twenty-five years, he became a member of the Masonic Blue Lodge of the village: he did not withdraw from membership until 1899, although it is believed that he long had been gone from Preston.

In the local newspapers of 1883 there appeared items, always with approbation, concerning Dr. Knowles' professional services in cases of various types. And in the *Chatfield Democrat* of September 1, 1883, there appeared the following note: "Dr. S. H. Knowles has resigned his position as County Physician. Here is an opportunity for some enterprising doctor to travel over the county, administer to the sick and furnish medicine, all for $300 a year." Finally, on November 29, 1883, the *National Republican* of Preston had this to say:

> S. H. Knowles left Preston yesterday for Omaha where he has entered into partnership with Dr. J. C. Deinse, an old and successful practicing physician having an immense practice. Dr. Knowles will have charge of the general practice, for which he is well qualified. The future of this young physician will be mainly successful. Few, if any, young men in his profession have attained his experiences and knowledge of the literature of medicine and surgery. Preston has suffered a serious loss in his leaving. His friends gave him a reception in Hamre Hall on Monday evening.

For what it may signify in this account, it should be stated that Dr. Seth Knowles, a graduate of the College of Physicians and Surgeons, of Keokuk, Iowa, in 1878 (if this was S. H. Knowles, he was twenty years old), was licensed to practice medicine in Minnesota on August 18, 1884, receiving certificate No. 944 (R) under the "Diploma Law" of 1883. It should be noted also that many physicians, although they promptly secured their licenses under the new law, did not file them promptly. By 1890 Dr. Seth Knowles was residing in Minneapolis, according to the 1883-1890 official register of physicians of Minnesota; he died prior to 1909, presumably before 1907, since his name does not appear in the first issue (1906) of the Directory of the American Medical Association.

(To be continued in the April issue.)

President's Letter

MINNESOTA MEDICAL SERVICE, INC., TO BEGIN OPERATION SHORTLY

Minnesota Medical Service, Incorporated, a nonprofit corporation, has been born and is now a living, vibrant organization. It was initiated by the Minnesota State Medical Association, but there is no business connection between the two organizations. During the period of nascency, which lasted almost two years, the committee on organization of medical service worked diligently. It obtained information from many sources and it studied the plans of organization and operation of similar corporations in other states. By this method it hoped to utilize the features of value of other plans and sought to avoid the errors which others have made. Finally the committee prepared the articles of incorporation, the proposed contracts and the schedule of benefits. In addition to this, it prepared an agreement with the Blue Cross and secured pledges from the physicians of Minnesota in order to finance the enterprise. These pledges exceeded $100,000.

After this task was completed, the committee on organization made its report before a special meeting of the House of Delegates of the Minnesota State Medical Association on December 22, 1946. Immediately following the formal acceptance of the report by the House of Delegates, the Council was instructed to proceed with the formation of the corporation. Accordingly, the incorporators were selected by the Council and they were requested to deal with the details incident to the creation of Minnesota Medical Service. Within a few days the articles of incorporation were filed and accepted. The directors of the corporation and its officers have been elected, and the pledges are being honored in a most gratifying manner. It is predicted that the pledges already made will be redeemed, and probably many physicians who did not respond to the first call will seek an opportunity to participate. In fact, many have already done so.

During the discussions which took place in the special meeting of the House of Delegates just mentioned, it became apparent that some of the members believed that an indemnity plan probably would be more acceptable than a service plan in some communities. Therefore, a second resolution was proposed and adopted which provided that the Council should appoint a committee of five members which should act as a liaison between the State Association and the insurance companies in order to develop plans for the provision of low-cost medical insurance on as broad a basis as possible. This committee was appointed without delay, and a short time thereafter it met with representatives of insurance companies. A similar liaison committee then was appointed by the insurance group and these two committees have been proceeding with their work.

Within a short time, Minnesota Medical Service, Incorporated, will be ready to perform its function. By this means, physicians of Minnesota are attempting to bring a high quality of medical care and provisions for hospitalization to everyone. As physicians set themselves to this task, they are aware that other schemes with similar purposes may present themselves. Their attitude toward such developments is one of complete co-operation as long as such schemes fulfill the requirements of the principles of ethics of the practice of medicine. They realize that probably no single plan will solve the entire problem, but they hope that through the Minnesota Medical Service Plan, a useful purpose will be served in bringing the proper kind of medical care to the infirm.

A great responsibility rests with physicians. Those who gave up so much to serve their country in the recent conflict, as well as those who remained at home, have borne heavy burdens during recent years. It is hoped that these new arrangements will lighten their burden. The prospective importance of this plan, like that of all new ideas and new discoveries, cannot be exaggerated but until it is accepted and used, it can exercise no influence and therefore can work no good. Minnesota Medical Service, Incorporated, will need the care and the interest of every practicing physician. No one can afford to adopt the attitude of complacency or apathy. Of all evils, probably torpor is one of the most deadly. It blunts the faculties of men, withers their powers and prevents effective progress. Since progress depends on the energy of man, our alertness in support of this plan must not slacken. We must maintain that vigor of character, that decisiveness and that audacity, both of conception and execution which alone will pave the way to achievement.

Louis A. Buie

President, Minnesota State Medical Association

CALORIE INTAKE AND INDUSTRIAL OUTPUT

Science* has published a simple understandable report out of war-ridden Germany that teaches obvious nutritional lessons, especially the need of adequate protein in order to maintain weight when dietary fats have to be curtailed. Dr. David B. Dill of Harvard University (Industrial Physiology and J. M. Corps, U. S. Army) brought this report back in late 1945. There was an opportunity in Germany to appraise the unit output of workers in quite standardized employments, and to observe the effect of decreases or increases in terms of essential food retrenchments or supplements. Whereas it was possible to add mineral and vitamin supplements, these were of no avail in the absence of basic foods and total calories consumed.

Thus, workers moving earth for an embankment or mining coal (succumbing to German exactitude and complaisance) furnished the scientists with a chance to prove that "rationing of food also means a rationing of industrial production." No doubt that is the source of much trouble in Britain today, as well as in much of the devastated world. "Reconstruction is a problem of calories," according to this report.

Coal miners in training were alloted 1,200 calories daily, out of a total of 2,800, for "work." They handled seven tons of coal daily or used up 170 calories per ton. The researchers advised adding 400 calories per day, and the output went up to nine tons daily at a unit expenditure of 155 calories. But at this level the workers averaged a weight loss of 1.2 kilograms in a period of six weeks, and, of course, that could not be long maintained. So they boosted the intake 800 calories, after which ten tons of coal were mined daily and the weights of the workers returned to normal.

It will immediately occur to many to ask about morale, living conditions, individual degrees of ambition or lethargy. For example we are inclined to think that people living in temperate zones become tired and languid, like the natives, when they move to tropical climates. Against this evidence is the experience of Stillwell's engineers using weak and tired Chinese coolies and putting the famous road over the Hump. They were not capable of heavy work until they were fed more or less like football players, and then their accomplishment was prodigious. Commenting on what happened in Germany when food became scarce, the authors add, "Under existing conditions the job of one man often has to be done by two or three with a resultant higher total wage cost."

The amount of American production in peace and in war stems in great degree from well-fed workers. We have a munificent soil, a virile people, and to these have been added the power of the machine. Despite the sending of vast supplies of food ($300,000,000 worth to our portion of occupied Germany alone, and a prospective three-fourths of a billion demand to carry them through 1948), we seem to have inspired envy far more than a desire to emulate our capitalistic motivated economy. The solemn facts of food should be pounded into the heads of politicians and peace planners. A world interchange of food and goods is needed far in advance of a dissemination of cockeyed ideas of rights, privileges, or ideologies.

E.L,T.

USE OF DIMERCAPROL (BAL)

Every physician who administers any type of arsenical should familarize himself with a new potent detoxifying agent (BAL). This was a result of war research and was developed in England to combat the injurious effects of lewisite gas, hence, the name British anti-lewisite, which was abbreviated to BAL. This chemical is 2, 3-dimercaptopropanol, a dithiol derivative. It has been shown that arsenic interferes with the pyruvate oxidation process of the tissues by attaching itself to the -SH groups which are essential for this reaction. BAL has a greater affinity for arsenic than these groups and, therefore, releases them and forms stable non-toxic compounds which are easily eliminated by the body.

---

*Kraut, H. A., and Muller (Dortmund, Germany); Calorie intake and industrial output, Science, 104:495, (Nov. 29) 1946.

BAL is able to prevent toxic reactions and to reverse the process if the tissue cells are not yet dead.

BAL is indicated in all toxic arsenical reactions such as neutralizing arsenical vesicant agents which come in contact with the skin or mucous membranes. Eagle* found marked relief and rapid improvement in the majority of cases of arsenical dermatitis in which BAL was used. It was a life-saving measure in toxic encephalitis and was beneficial in arsenical agranulocytosis, aplastic anemia, hepatitis, and accidental arsenic overdosage.

BAL is usually administered intramuscularly and, in the severe complications resulting from arsenic administration, the dosage found to be best suited is 3mg. per kg. This amount is given every four hours for twelve injections, then four injections are given on the third day, followed by injections twice daily until ten days have elapsed or complete recovery ensues. In less severe reactions, the amount given is 2.5 mgs. per kg. and, after the third day, only one to two injections a day, as indicated.

The reactions to BAL include nausea, vomiting, headache, burning of the mouth, throat and eyes, pain in the jaws, lacrimation and salivation, a constricted feeling of the throat and chest, and burning and tingling of the arms and legs. These occur about fifteen to twenty minutes after administration of the drug. Barbiturates seem to relieve these reactions and, if persistent, the dosage should be reduced.

Some investigators† have found BAL effective in heavy metal poisonings occurring from mercury, bismuth, gold, cadmium, zinc and lead. Its usage in these instances requires further study, and the exact methods of treatment are not yet available.

F. T. Becker, M.D.

VAGOTOMY FOR PEPTIC ULCER

WHATEVER the cause of peptic ulcer, the acid gastric secretion is generally accepted as being the main factor which prevents healing.

The main purpose of medical treatment of peptic ulcer is the constant neutralization of the acid gastric juice by frequent feedings and alkalis. This can be accomplished comparatively easily during waking hours but is well nigh impossible during the night. This is a distinct disadvantage, for a characteristic of the stomach in the presence of a peptic ulcer is that it secretes an abnormally large amount of gastric juice and possesses an increased motility during the fasting period.

It has been known since Pavlov's original experiments that the vagus is concerned with gastric secretion. A stomach isolated from the esophagus and duodenum by transection of the lower esophagus and duodenum, but with the vagus supply intact, will continue to secrete gastric juices. Section of the vagus fibres supplying the isolated stomach will result in a marked diminution in the quantity and acidity of the gastric secretion.

Dragstedt, recognizing this fact, was the first to propose and institute vagotomy in the treatment of peptic ulcer. His reports have stimulated others to follow his lead, and several hundred vagotomies have now been performed.

In Dragstedt's original operation, the transthoracic approach was used, the seventh or eighth left rib being resected. It was felt that only by this approach could the operator be sure of identifying and severing all of the vagus fibres which lie on the lower esophagus and are irregular in their course. Later he found that, with the abdominal approach, the terminal esophagus could be freed and retracted several centimeters, to make the right and left and communicating fibres accessible. The advantage of the abdominal approach is that the site of the ulcer can be inspected, and additional operative procedures can be undertaken at the same time if indicated. For, vagotomy alone is frequently not the cure for peptic ulcer. While it generally lowers stomach secretion and acidity and lessens motility, it not infrequently is followed by gastric stasis which requires constant gastric suction for one or more days following operation. If the ulcer has produced some narrowing of the pyloric outlet, a gastroenterostomy may also be required.

It is too early to make a fair appraisal of vagotomy in the treatment of peptic ulcer. Whether it is or is not the long-sought ideal operation for the surgical treatment of the disease cannot be stated. Certainly it is not indicated for every peptic ulcer. So-called medical treatment is highly satisfactory for most patients who are willing to co-operate in the matter of dieting, taking alkalis, and abstaining from coffee, alcohol and nicotine. Gastroenterostomy has relieved many a patient with recurrent ulcer and/or pyloric obstruction, although the incidence of resulting gastrojejunal ulcer is fairly high. Subtotal gastrectomy for recurrent and bleeding ulcer has proved fairly successful in the hands of a few surgeons but seems a rather formidable procedure.

---

*Eagle, H.: The Systemic Treatment of Arsenic Poisoning with BAL. J. Ven. Dis. Inform., 27:114, 1946.

†J. Clin. Investigation, July, 1946.

Vagotomy is apparently making a place for itself in the treatment of peptic ulcer. Perhaps it is particularly indicated in young individuals who, for one reason or another, do not respond to medical treatment and in whom hypersecretion of gastric juice is a prominent factor. Possibly it has a place along with gastroenterostomy. Until, however, indications for its use are more clear-cut, and long-time results of the operation have been observed, the members of the profession should not become too overenthusiastic in recommending it to their ulcer patients.

THE NURSING PROBLEM

THE great scarcity of registered nurses presents a problem dangerous and tragic to the hospitals, physicians and the public, both in urban and rural areas. The situation is truly alarming because it is certain to become much worse before it is better, as the supply of nurses is rapidly diminishing while the demand is increasing, chiefly because of the civil hospital expansion program and the vast construction for veterans.

The plain fact is that girls are not entering the nurses' training course as offered in our city hospitals. There are several elements entering into this situation. The ease with which high school graduates at present can secure satisfactory employment with little or no special training, and the proportional poor pay for well-trained nurses are two elements which are the result of war economy and will adjust themselves.

We in the rural areas are convinced that the chief element, which will not adjust itself, is the unnecessary costs and other demands made upon the girls in the courses offered in the cities today. We feel we have good grounds for criticism, as some years ago there were three-year nurses' training courses in many rural hospitals, two years spent at home and one year in a large city hospital, an arrangement which prepared excellent nurses in adequate supply. They proved themselves excellent because they were in great demand, both in the affiliate city hospitals and the country; also, the State Board examinations proved they were well grounded in the fundamentals as their average standing was high—very rarely did one fail. This desirable and successful arrangement was abitrarily terminated by some authority at the top. Some may say this was in the past but cannot be a success today. Facts prove the contrary.

In Minnesota we have three rural hospitals which have been able to carry on under the affiliation plan because of the consideration given them by the Sisters at St. Mary's Hospital in Duluth. These hospitals have more applicants than they can take, whereas most of the city hospitals have far less than half their needs. I can speak with first-hand knowledge concerning St. Francis Hospital, Breckenridge, a neighboring town. Sister Elizabeth tells me she regrets exceedingly that she is unable to take all her desirable applicants.

There are two chief reasons why the rural hospital courses are successful:

1. They are out where the desirable girls grow.

2. The courses are so arranged that the girls can earn their own way, aside from a few incidentals. Here a poor girl has an equal chance with those who have the means, resulting in better nurses.

The present plan of giving a one-year course for practical nurses and licensing them will help in certain ways, but does not meet the great need for more graduate nurses. We feel there is a solution to the pressing problem, namely, the establishment of nurses' training courses in properly equipped rural hospitals, with one-year affiliation in the large city hospital.

This is a plan that has succeeded and is now succeeding where given a chance. Why not push this plan through before the situation becomes hopeless?

W. L. Burnap, M.D.

Many a maternity patient has received obstetric care in its most literal sense—that is, care which is focused only on her reproductive organs—and died from tuberculosis or diabetes or cancer soon after delivery.—Hazel Corbin, R.N., J. Nursing, (Aug.) 1946.

Read before the National Conference on Rural Health at the Palmer House, Chicago, February 8, 1947.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

1947 NATIONAL HEALTH BILL

On February 10, the National Health Bill of 1947 was introduced to the Eightieth Congress as S. 545. This bill, sponsored by Republican Senators Taft of Ohio, Smith of New Jersey, Ball of Minnesota, and Donnell of Missouri, is a revised version of last year's Taft-Smith-Ball Bill, introduced toward the close of the Seventy-ninth Congress as an alternative to the Wagner-Murray-Dingell measure.

The 1947 National Health Bill is a great improvement over the former measure. New provisions have been added, and the basic philosophy behind the measure has been clarified. Helpful suggestions from members of the health, medical, hospital and dental professions, both those inside and outside of government circles, are responsible for much of this improvement.

Representatives of the American Medical Association met with Senators Taft, Ball and Smith on December 27; the following day, delegates from the New York Academy of Medicine and from the New Jersey State Medical Society met with Taft, Ball, Smith and Donnell. Representatives of the American Dental Association talked with Taft on January 7.

Bill Clearly Indicates Revenue Source

One aspect of S. 545 which should please doctors of medicine throughout the country is the definite provision in Section 307 of the bill, for an appropriation of funds from current revenues to carry out the program which the bill sets up. Section 307 was written into the bill largely at the instigation of Senator Donnell, who is a firm believer in financing from current revenues, as opposed to bond issues. Many have felt with Senator Donnell that the government has too long authorized appropriations without concern as to where the money is to come from.

A brief look at S. 545 reveals the following general provisions: (1) a grant of $200,000,000 a year to states on a population basis for medical care, chiefly to low-income patients, (2) establishment of a new and independent national health agency to handle all the federal government's health activities, (3) distribution of money for dental care with 8 million proposed for the first year and larger amounts each successive year up to 20 million the fourth year, (4) $10,000,000 for cancer control through the financing of diagnostic centers in the states, and (5) periodical medical examinations of all children in public, non-public, primary and secondary schools.

Measure to "Fill Gaps in Medical Service"

In a public statement made when he introduced his bill, Senator Taft said: "The bill we are proposing proceeds on the theory that the United States already had a comprehensive medical service as good as any in the world, but there are gaps in the service, particularly in reaching the lower income groups."

The Taft-Smith-Ball-Donnell Bill has been referred to the Committee on Labor and Public Welfare, of which Senator Taft is chairman, and Senators Ball, Smith and Donnell are members.

An important feature of S. 545 is its proposal to co-ördinate all health activities of the federal government into one independent agency. There is on foot in Washington a movement to put over another bill, which would create a health agency, but would place it in a subordinate position. This bill would set up a Welfare Department, give its head cabinet rank, and place under him three undersecretaries, one to manage health activities, one to take charge of welfare and social security and one to concern himself primarily with education.

Welfare Department vs. Health Agency

A complete analysis of the question of a three-cornered Welfare Department versus an Independent Health Agency has been made by Dr. Marjorie Shearon (Ph.D.), a non-partisan Washington research analyst.

The crux of the question, as Dr. Shearon sees it, is this: Does American Medicine want a third party between it and the President? If the top civilian medical and health officer were an undersecretary, she points out, that would mean he must discuss health and medical programs, legislation and policies with the President through an intermediary—someone, perhaps, from the welfare or social insurance fields.

In a recent issue of her regular Bulletin, "American Medicine and the Political Scene," which she authors in connection with her work as consultant on social legislation for Republican members of the Senate, Dr. Shearon discusses the question fully.

"An independent health agency has great merit," Dr. Shearon maintains. She explains that: (1) it would be founded on law, not created by order of the President; (2) it would be headed by a physician; (3) it would have its own funds from Congress, so that its director would not have to go "hat in hand" to a lay administrator annually for approval of his budget; and (4) it would be separated completely from the aggressive, autocratic Federal Security Agency in which the Social Security Administration is the dominant unit.

Political considerations aside, and speaking only for herself, on the basis of her observations, Dr. Shearon predicts that an undersecretary of health could easily become "only an also-ran," even though he might be an outstanding medical man.

Government "in Medical Picture to Stay"

"The Federal Government is in the medical picture to stay," Dr. Shearon declares. "It is up to American Medicine to determine whether its position in the family of federal agencies is to be strong or weak."

Dr. Shearon stresses the need for separation of health and medical functions from the control of the Federal Security Agency, calling this separation "the most important single objective to be sought at this time." The Taft-Smith-Ball-Donnell Bill calls for such a separation when it creates an independent health agency, responsible to the President and headed by an outstanding physician—thus it offers a way to protect highly technical health and medical functions of the Federal Government from lay control.

According to Dr. Shearon, Labor regards the Social Security Administration as its own agency—and so long as health and medical functions are a component part of a dominantly welfare-security agency, whether it be the Federal Security Administration or a Department of Health, Education and Security, Dr. Shearon warns that "American Medicine will face the triple threat of welfare workers, social insurance groups and organized Labor."

Grant of $4,119,800 Proposed for Minnesota

Minnesota's share of the $200,000,000 allotment proposed by the National Health Bill of 1947 would be $4,119,800. This money, in accordance with the underlying principles of the bill, represents aid to this and every other state to develop their own health and medical, hospital and dental services to low-income groups.

So that public money will be spent where most needed, part of each state's allocation is to be spent for a survey of resources in the fields covered by the bill. Participating states will be expected to develop comprehensive programs during a five-year period. Voluntary methods are encouraged through the provision for use of funds for at least partial payment of premiums for persons unable to pay in full for their own voluntary insurance.

The re-introduction in the Eightieth Congress of the storm-provoking Wagner-Murray-Dingell Bill of last year by Senator Murray of Montana promises a new fight between the proponents of compulsory health insurance as recommended by President Truman, and those who believe in the use of voluntary means for distributing medical services. A showdown is expected in the Senate Labor and Public Welfare committee, to which both the Taft-Smith-Ball-Donnell Bill and the reissued Wagner-Murray-Dingell Bill have been referred.

MINNESOTA HEALTH LEGISLATION

Health in Minnesota is getting its share of attention in the 1947 Legislature, and the hoppers contain several measures aimed at correcting and improving substandard conditions in certain areas, some of which have existed a long time.

For one example—all Minnesota communities that want full-time local health officers and other health personnel shall have them, providing a bill now under study by the legislators gets their ultimate approval. This bill will enable local governments to set up their own health departments or to pool their resources with those of adjacent counties and municipalities to form joint health departments.

Figures recently published in a State Department of Health bulletin, point to a need for just such a bill as this. Minnesota, the bulletin says, has been spending around 42 cents a year for each person for health services, an amount far from adequate to fill the health needs of the people. Considering that the majority of this sum is spent in urban areas of the state, at least a million people must do without their share of preventive health services.

Minnesota's 42-cent rate is one of the lowest in the United States, the average for the forty-eight states being about 61 cents per person annually—or 19 cents higher than the amount spent in Minnesota. The Department of Health says that about $1.00 per year per person is needed to provide even minimum health services.

Minnesota Late in Establishing County Health Departments

Minnesota is quite far down the line of states to formulate permissive legislation for the establishment of local health services; if the measure passes, it will be the forty-second state to take this step. A committee, known as the Minnesota Committee on Local Health Services, formed in 1945 and including representatives of many organizations—the State Medical, Dental and Nursing Associations, labor and farm groups, co-operatives, the PTA, the League of Women Voters, the Federation of Women's Clubs and others—has been at work since December, 1946, formulating basic principles to be embodied in a measure for submission to the 1947 Legislature.

That is the history behind Senate File No. 27, introduced by Senators Wright, Wahlstrand and Burdick, which provides for the appointment of full-time health officers and sharing of expense between participating counties on a population basis, and permits financing by federal, state and county funds, and private gifts.

The Wright-Wahlstrand-Burdick Bill, after its introduction, was referred to the Public Health Committees of the House and Senate. Already reported on favorably by the Senate Committee, the bill is due to be reported on shortly by the House Committee.

Seek Aid for Public Health Nurses

A measure to provide partial financial support for every county which hires a public health nurse is now before the Legislature and has been approved by the House of Representatives. It provides an annual grant to counties for public health nursing services, payment of which is to be made in quarterly installments.

A request for increased appropriations for state mental institutions, aimed at making the "purely custodial institution" a thing of the past in Minnesota is also being discussed by the lawmakers. The bill would increase facilities of our present institutions to provide more adequate treatment for mental patients in addition to supervision and care.

CANCER FIGHT INTENSIFIED

Minnesota's proposed allotment in the 1947 appropriation of $2,500,000 from the federal government for cancer control work is $52,665. With these funds and those collected by the Minnesota Cancer Society, the fight against cancer here in Minnesota, where over 4,000 lives were claimed by this disease last year, is growing ever more intense.

An alert State Cancer Committee, consisting of Dr. A. H. Wells of Duluth, chairman, and Drs. D. P. Anderson, Jr., Herbert Boysen, E. C. Hartley, J. A. Johnson, J. F. Karn, F. H. Magney, W. C. McCarty, Sr., Martin Nordland, W. A. O'Brien and W. T. Peyton, is expanding its already active educational program. Several conferences have been held for doctors, including clinics and demonstrations of newer methods for earlier diagnosis; for public health nurses, emphasizing methods of case-finding and follow-up care; and for lay leaders, presenting lectures on the nature of cancer, its cure and prevention, aimed at dispelling fear and spreading knowledge of the disease.

At the physicians' conference held on the campus of the University of Minnesota January 2, 3, and 4, a total of 125 doctors from Minnesota, North Dakota and South Dakota attended. Lay leaders attended a conference there January 23, 24, and 25.

Additional Conferences Scheduled

Conferences are scheduled for Duluth on March 18 and 20 and for Worthington on March 25. At future dates, it is planned to hold conferences in nine other sections of the state.

Through the Cancer Committee's arrangements, the Minnesota Cancer Society recently sent out to state physicians a booklet containing thirteen issues of the *Cancer Bulletin,* prepared by the American Cancer Society and containing articles, authored by specialists in the field, covering the latest-discovered facts about cancer, as it attacks various parts of the body, the lungs, the stomach, the bladder, the genito-urinary tract, et cetera. Starting about September, a series of monthly supplementary bulletins containing later information, which can be added to the booklet, will be sent to the doctors.

In line with recent action taken by a joint committee of the American Medical Association and the National Education Association to encourage the inclusion of a study of cancer in the nation's high schools, "A Revised Study Outline on Cancer for Secondary Schools" was prepared by the Minnesota Cancer Society and has been distributed to teachers in all public and private schools in the state.

Pamphlet Contains Cancer Facts

At its last session, the House of Delegates of the American Medical Association instructed the Council on Medical Service to make a survey of the ways in which funds for cancer control work are being utilized by the various state and county medical societies. Funds available are those provided by the federal government, distributed through the state departments of health and those coming from the American Cancer Society which are utilized by State Committees on Cancer. The American Medical Association wants to make sure that these funds are administered wisely with the co-operation of the practicing physician.

VETERANS MEDICAL SERVICE

With a little over half of the physicians in the state having returned their enrollment cards, making them participating physicians in the Minnesota Veterans Medical Service, this division of the State Association officially began operations, under Part I of the Uniform Fee Schedule, on February 10.

Already, a total of 500 authorizations for medical service to veterans have been received by the division from the Veterans Administration. Most of these have been authorizations for treatment, and some have been for physical examinations.

In a complex program of this kind, the beginnings are fraught with details and routines that must be worked out until each cog of the machinery is adjusted to work smoothly. Especially at this beginning stage, the doctors who are struggling through the rolls of red tape while trying to give the best possible service to the veteran, are turning in reports of services rendered, which in a few cases are not quite up to the requirements of the Veterans Administration. In these cases the VMS must write and ask the doctor for additional information. As the program progresses, of course, and doctors become accustomed to submitting these reports, there will be less and less of this difficulty. And it is assured, with the co-operation of the medical profession of this state, the VMS will not only satisfy the needs of the veteran but will also conform to government requirements.

ACUTE INTUSSUSCEPTION

(Continued from Page 260)

Summary

1. Fifty-six patients upon whom fifty-eight operations were done for acute intussusception were studied.

2. The cardinal symptoms were found to be intermittent colicky pain, vomiting and bloody stool. These were present in 73 per cent of the cases.

3. The best results were obtained where early diagnosis was made and early treatment instituted.

4. Close co-operation between the pediatrician and the surgeon is essential.

Minnesota Academy of Medicine

Meeting of November 13, 1946

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, November 13, 1946. Dinner was served at 7 o'clock, and the meeting was called to order at 8:15 by the president, Dr. S. E. Sweitzer.

There were fifty members and three visitors present.

Minutes of the October meeting were read and approved.

Upon ballot the following were elected as candidates for membership in the Academy: *University:* Drs. Donald Hastings and Leslie Spink; *Saint Paul:* Drs. Edward Burch and Jerome Hilger; *Minneapolis:* Drs. Ralph Creighton, Vernon Hart, Douglas Head, Stanley Maxeiner, and William Rucker.

The scientific program followed.

PERIARTERITIS NODOSUM—TREATMENT WITH PENICILLIN

S. MARX WHITE, M.D.
Minneapolis, Minnesota

Rich states that it has for some time been suspected that there may be a basic factor common to rheumatic fever, periarteritis nodosa, Henoch's and Schonlein's purpura, rheumatoid arthritis, lupus erythematosus, and quite probably some instances of glomerulonephritis. He further indicates that there are now many reasons for believing that all of these conditions may represent the effects of vascular and collagen injury caused by sensitization to a variety of different antigens. As a result of experimental study, Rich and Gregory report that typical diffuse periarteritis nodosa has been produced by establishing in rabbits a condition analogous to serum sickness in man and that the condition is one manifestation of the anaphylactic type of hypersensitivity. In previous papers they had presented clinical and pathological evidence that periarteritis nodosa has developed in patients as a result of hypersensitive reactions following foreign serum and sulfonamide therapy. As a result of their work, they state that the continued administration of foreign serum or sulfonamides after a hypersensitive reaction has occurred, or the injury of a single large amount of foreign serum, increases the danger of producing the vascular damage by prolonging the contact of the sensitized body with the offending antigen. As collateral evidence for the concept that vascular damage can be produced through hypersensitivity, they report that acute diffuse glomerulonephritis occurred in a number of the animals that developed a hypersensitive reaction to the foreign serum.

Much supportive information has been secured in recent years, an example of which is furnished by Wilson and Alexander. They report that in 300 consecutive cases of periarteritis nodosa, bronchial asthma was identified in fifty-four, or 18 per cent. Occasional apparent success in the treatment of severe asthma with bronchitis led to the suggestion that some effect might be produced by penicillin in the treatment of the case of periarteritis nodosa under discussion.

Case History

Mrs. M. P., aged seventy-three, was admitted to Eitel Hospital May 31, 1945. She was a widow, mother of three married children, one of them a surgeon in New York City. Her medical history is rich in modernistic medical and surgical procedures. The significant items include:

1. In 1936 a diagnosis was made of hypopituitarism and hypothyroidism with localized patches of a form of scleroderma. Basal metabolic rates quite uniformly in the neighborhood of minus 29 per cent; thyroid administration; also amniotin was used over a period of many months.

2. In November, 1936, uterine curettings secured because of post-menstrual bleeding showed senile endometrium with very thick-walled vessels but no evidence of malignancy.

3. In 1939, there was a diagnosis of anxiety neurosis with uterine prolapse.

4. The 1940 records show continued use of thyroid substance with basal metabolic levels between minus 5 and minus 10 per cent. In October, 1940, the labia majora and minora were excised. Microscopic examination showed marked atrophy of epithelium to the point of ulceration, subcutaneous tissues showing hyaline degeneration and round cell infiltration. A diagnosis of kraurosis vulvae was made. Postmenstrual bleeding from the uterus again indicated dilatation and curettage but the curettings showed no malignant changes.

5. In 1943, there were mild arthritic manifestations in the right knee and right index finger. The scleroderma became reactivated in the perineal region and stilbesterol, which she had been taking in minimal doses, was increased to 1 mgm. every three days.

She was admitted to Eitel Hospital on May 31, 1945, with a history of sudden onset May 28 with malaise, chills, vague body aches and pains. Following this, there was recurring chilliness and headache with fatigue. The day before admission she had difficulty in opening the mouth, with tenderness over the temporomandibular regions. There was no cough or dysuria. Examination in brief: She appeared moderately ill. There was definite swelling and tenderness of the parotid region on the left extending well below the angle of the mandible. On the right there was some swelling but less than on the left. The lungs were clear except for harsh breath sounds at the angle of the left scapula. The heart was negative except for frequent premature beats followed by compensatory pause. Blood pressure was 114/55. Electrocardiograms showed normal complexes with frequent extrasystoles from a single ventricular focus.

No rash was noted on the skin. The patellar and ankle reflexes were hyperactive but equal and normal. There was no rigidity of the neck or extremities. The impression was recorded that she had an epidemic parotitis and she was isolated.

However, with prompt subsidence of the local symptoms, daily temperatures rose to a maximum of 102.8° F.

at 4 to 8 p.m., with morning records of 99° to 100°. Occasional chilliness was noted when temperatures rose.

With persistence of the fever, studies were instituted. The urine was persistently negative. Leukocyte counts of 12,300 to 15,500 were recorded up to June 11. Myelocytes of all types constituted about 5 per cent of the leukocytes, and occasional plasma cells and leukoblasts were seen, but no myeloblasts. Heterophile antibody agglutination was atypical at 1:10 dilution. Agglutination with typhoid group and Brucella melitensis was negative.

Bone marrow biopsy, June 16, was reported by Dr. R. H. Reiff as showing neutrophilic hyperplasia of the marrow with inflammatory changes. The sedimentation rate of the red blood cells was 66 mm. in one hour.

X-ray studies showed no parenchymatous involvement in the lungs except a typical calcified Ghon tubercle in the lower left lung field. Minimal changes were noted on the vertebrae with calcifications on the walls of the aorta. There are minimal hypertrophic changes at the intervertebral joints and of the fingers.

On June 7, pain in both temporal regions was noted and there was very slight edema of the right temporal region, but nothing more than moderate tortuosity and diffuse thickening of the temporal arteries could be made out. The pain in the left parotid region was definitely diminished.

Ophthalmoscopic examination showed only sclerosis of retinal vessels consistent with her age.

On June 10, Dr. B. H. Morris noted complaint of pain in the right wrist with no local signs. Also noted—"Feels pain along the course of arm and leg veins," but there was no enlargement or tenderness over their course.

By June 18 and 19, there had been a period of lessened temperature, beginning June 16 with maxima of 100° F., and she was eating better, sitting up more, and seemed better in every way. There had been no specific therapy to which this could be assigned. At this moment she developed a throbbing pain in the right thumb with an area of swelling and redness on the radial aspect adjacent to the thumb nail and an area of redness and induration appeared on the skin lateral to the left breast. This area was about 1 cm. broad and 5 cm. long. It followed a course downward and toward the median line such as would be typical of a small superficial artery. The area was not particularly tender although the breasts were very tender and there was a general hypersensitivity both of skin and muscles. By this time, repeated blood cultures were still showing no growth (and none appeared at any time later).

On June 27 biopsy material was secured from the skin lesion and from the left deltoid muscle. Microscopic report by Dr. R. W. Koucky: The deltoid region showed no vascular lesions. The characteristic change was seen only in the subcutaneous tissue. The process affected the small arteries and an occasional arteriole. These small arteries showed thrombosis and marked thickening of the subintimal layer. All of the muscle and periarterial zone was overgrown by young fibroblasts. There was heavy, diffuse infiltration of polymorphonuclears. There were syncitial masses like malformed giant cells. The picture was typical throughout of periarteritis nodosum with the exception that the heavy eosinophilia customarily seen was absent in this case. Conclusion: Periarteritis nodosum. (Slides shown)

On the day of admission, May 31, 1945, penicillin intramuscularly had been started by a penicillin-conscious assistant but was discontinued after thirty doses at three-hour intervals and a total of 600,000 units. No effect on the fever or symptoms was noted at this time.

Following the diagnosis of periarteritis and despite the indications apparently unfavorable to its use, penicillin intramuscularly was again begun on June 28. Daily amounts of 160,000 units was given over a period of twenty-one days to July 19, with a total of 1,920,000 units. During the first fourteen days of penicillin therapy temperature rises to 103° F. continued. Then there followed prompt abatement but only to 100° and 101° F. maxima until discontinuance on July 19. During the week of July 20-27, on two occasions only, records up to 101.6° were noted, and after this time to August 19, i.e., one month, temperatures up to 100° F. were occasionally recorded. From then on to discharge on September 6 the temperature was normal, and she gradually gained in strength and capacity.

During the period of penicillin administration, transfusions from Rh negative donors were given on three occasions in amounts of 300 c.c. each, with no reactions. Hemoglobin values around 75 per cent remained essentially unchanged. When seen after discharged, on October 2, 1945, the hemoglobin was 75 per cent, red cells 3,200,000, and leukocytes 11,400.

The winter of 1945-1946 was spent in California. While there she had a relapse, the story being strongly suggestive of her old trouble outlined above. In the account of this illness, she reports that on her insistence penicillin and five transfusions were again used with slow recovery. A letter from Dr. William H. Leake, Beverly Hills, California, may be quoted as follows: "Your patient, Mrs. M. P., was under treatment at Hollywood-Presbyterian Hospital between May 4 and June 21, 1946. She received five whole blood transfusions of 300-350 c.c. each on the following dates: May 13, 14, 16, 21, and 29. Over an eleven-day period, May 10 to May 21, 700,000 units of penicillin were administered. Shortly after this treatment was instituted definite improvement was noted in the patient's condition."

She was readmitted to Eitel Hospital on October 3, 1946. She complained of the same vague pains but had no skin eruptions and no localizing symptoms. There was much headache which she insisted was similar to that she had had during her previous hospital stay. There was extreme weakness, and she continually insisted that her symptoms were identical with those of 1945 and with those during her hospitalization in California in the winter of 1945-46. She was insistent that penicillin and transfusions be tried. During her stay no rise in temperature was recorded. The blood pressure was 120/80, weight 144 pounds; general physical examination negative.

On October 4 her hemoglobin was 80 per cent (13.3 grams) with a leukocyte count of 6,000. On October 8, hemoglobin 88 per cent (14.7 grams) with red count of 4,680,000; and October 10, hemoglobin 85 per cent, red count 4,450,000, and leukocytes 6,850. Examination of the urine gave negative findings.

Penicillin in doses of 25,000 units intramuscularly at three-hour intervals up to and including October 15 was given to a total of 2,500,000 units. She was given transfusions of 250 c.c. of blood on October 7 and October 12.

During the hospital stay her headaches disappeared, vague pains no longer were troublesome, and she improved in strength and well-being at a moderate rate so that on the date of discharge, October 15, 1946, she was feeling well, walking about and said that she had improved very greatly. She has remained well and is going about quite regularly.

It should be stated here that she has not been on thyroid or estrogen therapy for nearly two years. No identifiable allergen has been found in her case.

Discussion

Dr. A. R. Hall, Saint Paul: This is an interesting contribution. Dr. White reports a case of periarteritis nodosa which was benefited and possibly cured by treatment with penicillin. Periarteritis nodosum has been considered a condition in which the mortality is very high. However, in most cases some of the lesions histologically show evidence of regeneration.

I like the change of the name from periarteritis nodosum to arteritis nodosum since it is more descriptive of the pathological findings.

What is arteritis nodosum? Is it a disease entity or is it a tissue reaction which may be due to different causative agents? This woman was benefited by penicillin. Penicillin is apparently of benefit in bacterial infections only. If this is true, we are perhaps justified in thinking that in this case the causative agent was bacterial infection. If we may add this case of possible bacterial infection to the growing list of etiological factors which have been reported as causing arteritis nodosum, we have added to our understanding of these pathological changes. Rich has reported finding arteritis nodosum in patients who had been treated by the sulfonamides, by iodine, etc., and has produced it experimentally by the injection of foreign proteids. Selye had produced arteritis nodosum in rats by the injection of adrenal cortex.

It seems that we should classify arteritis nodosum as a tissue change which may be produced by many quite different agents.

Dr. J. A. Lepak, Saint Paul: I should like to ask Dr. White whether any effort was made to isolate or culture an organism from the removel tissue?

Dr. White, closing: There was no effort made to isolate any organism. I have been impressed, in trying to get what information we have on this case, by the welter of evidence coming forth at this time that periarteritis, or better—arteritis nodosum, is a systemic reaction, allergic in character, and by its relationship to asthma; that the relationship that Alex Wilson showed to asthma is very suggestive. One interesting point is that in some of the cases of periarteritis associated with asthma a marked eosinophilia was found in the tissues. Some of the cases reported with asthma do not show these changes in the tissues. Eosinophilia is not shown in the tissues in the biopsy material in the present case.

THE TREATMENT OF HYSTERIA BY NARCO-HYPNOSIS

HEWITT B. HANNAH, M.D.
Minneapolis, Minnesota

There is no branch of medicine which is attracting the attention at the present time of both medical men and lay people more than the neuroses and so-called psychosomatic medicine. It is estimated that one-third of all patients who consult a physician do not have any definite bodily disease to account for their complaints. There is another one-third of the patients who have some bodily disease but their symptoms are not explained by the disease or they are out of proportion to any discoverable pathological disease. We can, therefore, readily see what an important role emotional factors must play in the practice of medicine.

It was about a century ago that Virchow introduced the structural conception of disease and this led to a consideration of disease as a disturbance or change in the structural cells and organs. This was the foundation of gross and histological pathology. Diseases were then divided into different components of ailments and this caused the development of the various specialties and specialists and the introduction of machines of precision for diagnosis. In other words, we had the machine age and the assembly line in medicine. Out of this grew the clinic idea of the practice of medicine.

During this period of mechanical and laboratory development, many essential discoveries were made which have permitted us to better understand, diagnose and treat the structural and biochemical disturbances of the body. During this age of mechanical development the emotional and psychological background of the patient was lost and even the phase of his illness was many times held in utter contempt by many doctors.

There has been a definite change in the attitude of physicians during the past ten years and the pendulum is swinging so that again there is marked interest being shown everywhere in the so-called functional disturbances. At this point, however, I want to emphasize the importance of thoroughly studying the patient from the organic standpoint to be sure he has no structural disease before he is branded as a neurasthenic, an anxiety state, or a case of hysteria.

The treatment of the psychoneurotic often leads to gratifying results but in such treatment the art of medicine comes to the fore and the personality of the doctor is still an important factor. There must be a never failing and kindly interest in the patient, and the doctor should not complain of becoming tired of his patient.

The physician must take a very careful and thorough history and develop all the conscious emotional complications that are present or have been present in the past. This usually takes more than one interview and the physician should see the patient many times, get to know him and gain his confidence.

Freud and his coworkers and followers have pointed out that there are many emotional traumas which have occurred in early life, as well as frustrations or repressions which have been buried in the unconscious mind and produce states of nervous tension and hysterical symptoms. It was out of Freud's concept that the system of psychoanalysis was developed so that these repressions, frustrations and emotional traumae could be released and brought out into the open conscious state. However, the psychoanalytic methods were long, tedious, and expensive, and very few men were trained or had experience to carry on the procedure.

It was during the present war that the procedure of producing a trance state or a state of hypnosis by drugs was used. This semi-sleep state has recently been referred to as narco-analysis. The drugs used have been sodium amytal, sodium pentobarbital, and sodium pentothal. The patient is not given enough of the drug to produce deep sleep but he is in a dream state or a semisleep state, or in a trance. The theory is that the drugs slow down respiration and there is reduced consumption of oxygen by the brain cells and a mild state of anoxemia results.

I am going to report a series of selected cases which have been treated by narco-analysis. The method used

---

Inaugural thesis.

is to dissolve 7.5 grains of one of the above-mentioned drugs in 20 c.c. of distilled sterile water. A platinum needle is used to prevent coagulation of blood aspirated from the vein when the injection is stopped without withdrawing the needle. The patient is placed in a semi-darkened room on a comfortable bed. No one else is present in the room except the patient and the physician. The injection is made very slowly and as soon as the patient complains of a numb feeling in the roof of his mouth, a slightly dizzy feeling, and a slightly drowsy feeling, the injection is stopped. The patient is able to hear what is said to him, is able to talk clearly and to answer questions distinctly.

While more barbiturate is being injected in order to keep him in this semi-sleep state, a closer hypnotic relationship is established between the patient and the physician. There is a free association of ideas. There is abnormal or extreme retentiveness of memory. Smallest details of information are related, which may seem trivial, and these become useful. Latent and repressed conflicts come to the surface. The history of mental suffering regains clarity and abnormal ideation becomes amplified. The physician obtains a quantity of information about the patient's mental state which could not be obtained during a much longer time with the usual methods. The length of time involved in a treatment may be as much as two or three hours. Every effort should be made to make the patient accept consciously the material which was obtained from his subconscious mind. This will render him more capable of viewing the past trauma in a sensible manner.

The following cases will explain more in detail the method involved.

Case 1.—A man twenty-two years of age, unmarried, was brought in six years ago by ambulance from another city. He would not talk, open his mouth, or move his arms or legs. He would only sit in a chair, with his eyes closed. He defecated and urinated in the chair or in bed. He had to be dressed, undressed, and carried into the bathtub. He would not open his mouth to eat and had to be tube fed. There was a history of acute onset about two weeks previously, and also a history of a somewhat bashful fellow who was a good student in school and conscientious in his work. He was a college graduate and his occupation was that of a pharmacist. He was observed for several weeks, and there was no improvement. He was tube fed during this time. Our impression was one of an acute attack of schizophrenia of the catatonic type.

Fifteen grains of sodium amytal were dissolved in 20 c.c. of sterile distilled water and injected slowly into his vein at the elbow. After a few c.c. were injected, the patient opened his eyes and looked around. He was asked questions, was encouraged to talk, and slowly unfolded the following story. About one year previously, he was taken, one evening, by a bunch of fellows by force as he was leaving the drug store to a house of prostitution. He was undressed, placed in a room with a group of nude girls, and the fellows were also present. The girls coaxed him to have relations with them but he refused, and then they attempted all sorts of perverted practices upon him. He said he was terribly frightened, his heart beat rapidly, he perspired and could not talk. They kept him there for several hours, then dressed him and pushed him out the front door. He found his way home, was in a very nervous state, and was afraid his parents would find out what had happened. The same fellows continued to come around the drug store, teasing him about the matter, and threatening to do it over again. He lived in constant anxiety and fear until he said one day it seemed as if he was unable to think, or to move or to talk. He related that he wanted to talk, to obey instructions, to go to the bathroom and to eat his meals, but he could not. In this dream state he was assured that he would be all right, and further sodium amytal was injected until he went to sleep.

Upon awakening, he got up out of bed, went to the bathroom, carried on a conversation with the nurses in a normal manner. He remained in the hospital for several weeks and I discussed the matter fully with him but never referred to what he related to me with anyone else. Six years have now elapsed. In the meantime he has married and I have seen him on numerous occasions. He has never had a recurrence.

Case 2.—This patient is a twenty-four-year-old married woman who has two children, six and four years of age. She had a high school education. Her general health had been good and she had had no operations.

Her present complaint was that of slapping her chest with the right hand, over a period of six years. This came on during the time she was pregnant with her first child. The previous diagnosis had been one of postencephalitic syndrome. A neurological examination was negative except for this constant slapping of the right side of the chest with the right hand during her waking hours. The spinal fluid examination was negative. She had been treated with rabellon, stromonium, and sedatives.

I saw her on frequent occasions over a period of six months and could not elicit from her anything of an emotional character in her past history. It was my impression that the constant slapping of the right hand against the chest was not due to any organic disease of the central nervous system. She was finally hospitalized and given pentobarbital sodium intravenously. After a few c.c. were injected, the slapping ceased and she became very quiet. She complained of a numb feeling in the roof of her mouth and she said she had a feeling of well-being. She was then asked what had been bothering her or what had happened to upset her and make her nervous. She said that when she was a senior in high school she was going with two boys. She had had sexual relations with both of these boys. One month she did not menstruate and she knew she must be pregnant but she did not know which boy was the father. She was frightened about her condition and was afraid to tell her mother who was a strict disciplinarian and unduly religious. She did not know which boy she wanted to marry or which one she should blame for her pregnancy. Her nervousness increased and she finally decided to choose one of the boys and get married. She told the boy and they eloped and were married. Each boy did not know about the other boy having had relations with her. They came home after the marriage and announced their marriage to their respective families but did not tell of the pregnancy. About this time she noticed some shaking of her right hand and this continued to get worse during her pregnancy. Up to this time no one except her husband had ever been informed that pregnancy started before marriage. She had also never informed her husband of the other fellow and the possibility that the child did not belong to him. She stated that she lived in constant fear during these years that her husband might in some way find out about the whole matter and also that her mother might find out that she had been pregnant before her marriage. The twilight state was continued for about two hours in order to receive all of this history. She was told that the slapping of her right hand had come about because of all this emotional conflict and that when she awakened it would all be gone. Enough pentobarbital was given to her so that she went to sleep. Twelve hours later when she awakened, she was nauseated and vomited, but there was no subsequent tremor or slapping of the right arm and hand. The whole matter has been discussed with her subsequently. She has gained weight and is getting along satisfactorily at home. Eighteen months have now elapsed without any return of symptoms.

Case 3.—A married man, aged fifty-two, government employe, lives in a small city. He was brought to my office in a wheel chair. He had not walked for five years. The history was that five years previously, on a cold winter morning, he was on his way to the office when he slipped and fell on the sidewalk. He had a pain in his back and in one hip, but after a short while he got up. He walked eight or ten blocks to his office, attended to some work, and then went to a luncheon meeting at a hotel. During the time he was at the luncheon meeting he had a weak feeling, and perspired. After lunch he walked into the lobby of the hotel and sat down because his legs were getting weak. He was taken home in a cab and by the time he reached home his legs had become very rigid. He was taken to a hospital where x-rays of his spine, pelvis, and hip joints showed no abnormalities. A spinal fluid was negative. He was told by one of the attending physicians that he had experienced damage to his spinal cord and that he would probably never be able to walk again.

At the time I first saw him, the neurological examination showed no sensory disturbance, no difficulty in bowel or bladder control, no great toe signs, no angle or patellar clonus, and the deep reflexes were within normal limits. The muscles of the legs were held flexed at the knees and in a state of spasm but the degree of spasm was not like an organic spasm but seemed to be to some degree intermittent. Another spinal fluid was negative.

He was put in the hospital, given a small amount of pentobarbital sodium and in a few moments his muscles were completely relaxed and he then told me how frightened he was when he fell down. He thought he could not get up, that he would freeze to death before any one would find him. On the way to the luncheon meeting his heart pounded in his chest, he perspired profusely, and a peculiar sensation came over him. In the trance state, he moved his legs freely in bed, we got him out of bed and he walked down the corridor of the hospital and back to bed. As he walked down the corridor, the syringe and needle were kept intact in his vein. He returned to bed, we gave him some further barbiturate and he went to sleep. Within two hours he wakened and his legs still had fairly normal tone and he moved them around in bed. However, within another couple of hours his legs gradually became spastic again. We repeated the treatment on at least a dozen occasions and several times were able to get him to walk up and down stairs and go onto another floor of the hospital. On at least one occasion the spasm did not return until about four hours after he wakened, and during this time he walked around in the hospital without any help. During his conscious state and before the spasm recurred, I discussed the whole matter with him but each time he would tell me that eventually his legs would become spastic again.

I consider this case a failure, but a most interesting experiment.

Case 4.—A married woman, fifty-five years of age, without any children, suddenly lost her voice about eighteen months before I saw her. Her husband accompanied her to the office and could give no explanation for her aphonia. The only way I could interview her was to write the questions, and she gave me the answers in writing. I could get no past history of instability from her husband. He stated he had come home from a business trip and found his wife speechless. They lived in another state, and she had been treated with vitamins, throat sprays, and by osteopaths and chiropractors.

The neurological examination was entirely negative. There was nothing in the physical examination of any consequence. I sent her to a very competent nose and throat man, and he reported to me that he could find no evidence of any disease of her larynx and that there was no paralysis of the vocal cords.

Under narco-hypnosis she gradually began to talk; at first she only whispered and then gradually the volume and quality improved. She stated that she lived alone and that her husband was gone on business for protracted periods of time. They never had any children and she was very much attached to her husband. Over a period of years on four or five occasions her husband had suffered attacks of hemorrhage from a duodenal ulcer. While out on the road he would have to be hospitalized and she would get a telephone call to go and see him in some distant town. She said she lived in constant fear that he would die in one of these attacks. About two months before her aphonia occurred, he had had another attack, was urged to have an operation, and had refused. She was terribly frightened over the prospective surgery and what might happen to him. She was also afraid he would die as a result of one of the hemorrhages. The day before he arrived home, the telephone rang and she could not talk when she picked up the receiver. She had not talked since. The whole situation was one of fear and anxiety, and her own worry her husband's possible death from either operation or recurring hemorrhage. Her loss of voice was a conversion type of hysteria which arose out of this conflict. Upon awakening she talked in a mild, low tone of voice, and during the next week her ordinary voice returned to its normal state. The whole matter was discussed frankly with her after the narco-hypnotic treatment was over.

Nine months have now gone by and she has had no more difficulty. Her husband has not had any surgery done and he has had no further hemorrhages.

Case 5.—A widow in her late fifties, who had been employed for many years as a clerk for the Soo Line, had not talked for about a year when I saw her two years ago. She had been treated for chronic laryngitis without any benefit. I had her examined by Dr. Larry Boies, and he found her vocal cords to be normal.

Her neurological and physical examinations were negative.

She was given pentothal sodium, and in the trance state she told me about the death of her husband some ten years ago. She was left with a daughter in her teens. After the death of her husband she had to go to work. She was very much attached to her daughter. The daughter had finished high school and was working and they were getting along very well. Two years before I saw her the daughter developed acute appendicitis and was operated upon. She got along very well in the hospital and was taken home on the eighth day. As she was taken from the automobile into the home, she slumped over and was dead when she was finally brought into the house. The mother was with her at the time. The mother told me that some time later during the day she had a queer feeling come over her and she could not make a sound.

After she awakened from the sleep, she talked normally and continued to talk in a normal manner. I heard from her frequently until April of 1946 when I received word that she had died suddenly and that an autopsy showed a coronary thrombosis.

Case 6.—This is the case of another middle-aged woman with an hysterical aphonia who was seen by Dr. George Tangen, who is associated with Dr. Boies. He was unable to find any disease of the larynx.

The physical and neurological examinations were negative, and the spinal fluid was negative. The underlying problem of an emotional character was the drinking and gambling of her husband and also her only child, a daughter, who was married to a man whom she did not like. She regained her voice and was all right for a month and then lost her voice again. She returned for further therapy. She regained the use of her voice for another three months and now she cannot talk again. The underlying problem with her husband and her daughter still remains the same.

Case 7.—A married man, aged thirty-two was referred to me by an insurance company, because of intermittent jerkings of both arms and legs. These jerkings occur every afternoon and evening.

This man fell down a church steeple in Duluth, a distance of 80 feet, in 1940. He landed on a salamander. He fractured his pelvis and one hip, and received some third degree burns on his back. He was hospitalized a long time and finally left the hospital after almost a year's stay. Sometime later in 1942, he had an occasional muscle twitching in his body which occurred toward the end of the day. He was married in 1942 and he has one child. He has been able to work but toward the end of each day, this intermittent jerking occurs. He stated that doctors had told him it was the nervous shock from the fall.

The neurological examination was again negative except for the body jerking.

Under narco-hypnosis he told me the following story. While in the hospital following the accident, he fell in love with his special nurse and after he left the hospital he saw her frequently and wanted to marry her. He had sex relations with her quite frequently. However, she did not want to marry him, and she went east to get another position. While the nurse was gone he met his wife and married her, although he was not in love with her. His wife is frigid and rather quiet. Her family visits them a great deal and he dislikes it. All in all, he is unhappily married. His wife does not know about the other girl. He stated that while at work he does not have to think of the other girl but when he comes home at night he sits down and dreams about her. He also stated that when he thinks of the nurse he almost always has the picture of himself falling down the steeple. Then he seems to jerk his body.

While under narco-analysis, the whole thing was discussed with him from an emotional and intellectual standpoint. He has had three treatments and was seen several times between treatments. The whole matter was discussed with him, and he now seldom has any jerking.

Case 8.—This was an unmarried woman, forty-two years of age, who was referred to me by an orthopedist. She had an excellent position with one of the advertising agencies in the Twin Cities. Her immediate complaint was that when she walked, she turned her head toward the left. This never occurred when she was sitting or standing, but as soon as she started to walk her head would turn to the left. If she put the tip of a finger against her chin, then her head would not turn. If she walked with a pencil or a cigarette in her mouth, then her head did not turn to the left. Even if she had a thread between her lips when she walked, her head did not turn.

This woman had been examined and re-examined by various competent people and no explanation had been given her for this turning of the head except she was told it was a habit.

Under pentothal sodium she related a long series of emotional difficulties in her past life. When she was fifteen years old her local neighborhood butcher attempted to have sexual relations with her in the back part of the butcher shop. She says she was terribly frightened and never told anyone.

Later, she met a man in Iowa, was engaged to him, had relations with him, but the engagement was broken off. Subsequently this man went to Chicago and was married. Some years later, our patient met him again in Chicago and over a period of time they carried on illicit relations. She told me that she had to be transferred to another city in order to get away from him. When she reached another city, she got along in a satisfactory manner for a while until she met a group of men and women. At a party one night, the lights in the house all went out and she realized that everyone there was having sexual relations. The fellow she was with attempted to have relations with her but she would not have anything to do with him. When the lights finally came on the rest of the members of the party made fun of her and she was in a very embarrassing position. A few days after this experience, she noted the phenomena of her head turning to the left. It took some two to three hours for her to relate all of her experiences in the past.

A week later she returned to the hospital and remained another twenty-four hours and was given another injection of pentothal sodium. She related many of the details of her past experiences again and added others to them. Subsequently I saw her several times in my office and we went over all the experiences which she had related to me under narco-hypnosis. Three months have now elapsed and the last time I saw her she told me there was no more turning of her head to the left. She does not have to put a pencil in her mouth or smoke a cigarette or put the tip of a finger to her chin in order to keep her head from turning.

Case 9.—This is the case of a twenty-five-year-old ex-service man who awakened every night between 1:00 and 5:00 A.M. with pain in his left lower abdomen. He would get up and walk the floor or take a hot bath or smoke cigarettes for a couple of hours. The pain was intermittent in character. He had been examined by the army and by several clinics, and a diagnosis of a functional neurosis had been made. He was the son-in-law of a physician, and the physician had gone to no end of trouble in trying to find some organic basis for this pain.

Under narco-hypnosis the patient told of a very exciting experience, when he was about twelve years old, which occurred on the north shore of Lake Superior. He was in a cabin with his parents when lightning struck the cabin and it partially burned during a heavy rain storm. He became very tense and nervous, could not talk, and had to be carried into another bed. Following this experience, he stated that he had always been very tense and unable to relax. When he was attending the university, he would be very much upset at the time of examinations. He finally went into the army and was in the air corps. Every time he had to make a flight, and especially if the flight was at night, he was very distressed and when the plane landed he would frequently be unable to get out of the plane for a matter of five to ten minutes. It was while he was in the Pacific that he began to have the attacks of pain in his abdomen at night.

This fellow has had three treatments, and the pain has disappeared at night. He is still having attacks of pain to a lesser degree in the daytime and still has a feeling of nervousness and tenseness.

Case 10.—This woman, whom I have seen recently, is about fifty years of age. She shrugs her shoulders. This shrugging of her shoulders occurs during the daytime but is gone during sleep.

Under drug hypnosis, she told about her husband's drinking, gambling, going out with other women, and how her only daughter had become pregnant and had a baby out of wedlock. She is still in the hospital and the shrugging of her shoulders has not entirely disappeared, but she is much better.

Conclusions

1. Drug hypnosis is very valuable in obtaining history which otherwise could not be obtained.

2. It brings out of the unconscious many emotional conflicts, repressions and frustrations. It gives one an

opportunity to discuss these matters with the patient and synthesize them in the conscious state.

3. It is not a cure-all for functional nervous cases but it is certainly of great value in selected cases of conversion hysteria where other methods have failed.

4. All cases of conversion hysteria do not respond to this type of treatment but there is a sufficient number of cases which do respond to make it a very valuable therapeutic measure.

Discussion

Dr. Hannah: There is another feature in narcohypnosis that offers a very interesting future. A man, recently referred to me by the United States Shipping Corporation, complained of inability to hear when he was tested on the audiogram. The audiogram showed an 80 per cent loss of hearing in each ear. However, this man could hear ordinary conversation without much difficulty. In conjunction with one of the otologists, we put this man through the tests when he was in a state of narcohypnosis. In this state, he could hear very much better, and the loss of hearing was only about 20 per cent. This test was repeated under narco-hypnosis four times with practically the same results. When the man awakened four hours later, he had no memory of the tests.

This offers a very fruitful field for determining alleged loss of hearing or loss of sight in medicolegal matters.

The meeting was adjourned.

A. E. Cardle, *Secretary*

POLIO COSTS IN MINNESOTA

Approximately $2,000,000 will have been expended in Minnesota by the National Foundation for Infantile Paralysis to combat the 1946 polio epidemic before the last case can be considered closed, according to Charles B. Rogers, state campaign chairman for the annual "March of Dimes." This total represents half of the epidemic emergency fund for the National Foundation and more than two times the contributions of Minnesota residents to the "March of Dimes" since it was launched in 1938.

This sum represents costs of medical, nursing and physical therapy care, hospital bills, salaries and maintenance of nurses, and equipment. More than 900 nurses, 40 physical therapists, two epidemiologists, 43 respirators, 60 hot pack machines, 18 suction machines, and some 2,400 pounds of wool for hot packs were sent into Minnesota during the epidemic. Personnel and equipment were rushed in by planes, trucks and trains.

"Next to the Minneapolis General Hospital," Mr. Rogers reports, "the Kenny Institute received the largest contributions of any of the six Minneapolis hospitals used for the care of polio patients—more than $46,000. In addition, more than $24,000 of doctor and hospital bills were paid for patients who received the Kenny treatment in the Kenny Institute."

The University of Minnesota, since 1938, has been granted $699,243 by the National Foundation for investigation, research, and short courses for physicians, nurses and physical therapists.—*Bulletin*, Hennepin County Medical Society, January, 1947.

GETTING THE MOST FROM A PATHOLOGIST

(Continued from Page 279)

Most of the autopsies in the country today are being done by relatively untrained and inexperienced men. Attention to detail is of first importance. The cause of death will be found in the great majority of cases without microscopic study, but sections will add greatly to confidence in gross conclusions. A few blocks of tissue in 10 per cent formalin can be submitted to the pathologist, along with a copy of the clinical history and gross findings. With knowledge of the diagnostic problem at hand, he will prepare a tissue report with relevant information. The doctor should always request these slides and study them.

If the autopsy problem is one of possible poisoning, the tissue must not be formalized. Generous specimens of blood, urine, heart, liver, spleen, brain, stomach, and gastric contents, are packed in ice and sent either to the coroner of Hennepin or Ramsey county or to a toxicologic laboratory recommended by him. There are very few good laboratories of this type in the state. The University of Minnesota has no facilities for toxicologic diagnosis.

It has been the intention of this paper to present some of the advantages and shortcomings of pathologic examination and to suggest that too little information is forwarded with specimens. The pathologist can profitably use clinical findings when studying tissue but usually is forced to do without them. The clinician who wants the ultimate in diagnostic accuracy will properly prepare his tissues for examination and will write a history. The preparation of such a report to accompany each specimen consolidates the ideas of the doctor and stimulates the interest of the pathologist.

The single flaw in the remarkable progress in the control of tuberculosis in the United States is the fact that the disease is still a major cause of death, killing more Americans than all other infectious and parasitic diseases combined. In spite of a constant search for drugs to effect a lasting cure, no substance has been found that is completely satisfactory. Various sulfonamides, although capable of modifying the disease in experimental animals, have proved too toxic for continuous use in human patients, and streptomycin, which provides considerable protection, has not effected permanent cure. Since no specific remedy has been discovered, the accepted methods of treatment which have obtained excellent results in a great many cases, must be relied on. Editorial, New England J. Med., (Dec. 5) 1946.

Stated Meeting Held December 5, 1946

The President, Thomas J. Kinsella, M.D., in the chair

SURGICAL MANAGEMENT OF CHRONIC FISTULAS OF THE RECTUM FOLLOWING PENETRATING WOUNDS

ROBERT J. TENNER, M.D., F.A.C.S.
Minneapolis, Minnesota

This paper presents a discussion of sequelae of a type of injury which fortunately is rare in civilian practice, but which was a not infrequent occurrence during this past war. It deals with injuries to the infraperitoneal portion of the colon which were caused by missiles entering the dorsum of the body, penetrating the rectum, and resulting in persistent chronic fistulas in this region.

Much has been written recently regarding wounds of the rectum and infraperitoneal portion of the large bowel. The initial surgical treatment and the definitive treatment have been discussed in detail. Nevertheless, I wish to describe my experienc in the surgical management of seven cases of this type of fistula. By chronic fistulas is meant such as have persisted for three to five months since injury despite diversion of the fecal stream by colostomy. Such fistulas communicated in all instances with the posterior or posterolateral portion of the extraperitoneal rectum, and the external openings were found in the sacrococcygeal and right and left buttocks regions at the location of wounds of entry of the missiles.

When first seen, such patients all had good functioning colostomies and their chronic fistulas were apparent on the dorsum of the body. In some cases there was a healed, depressed, firm, fixed scar on the right or left buttocks, in the center of which the external orfice of the fistulous tract could be seen; in others there was a clean granulating wound, in which the fistulous tract opening could be identified. On evaluating the direction, depth and extensiveness of the fistulous tract, several diagnostic measures were used including barium enema (to check patency of the distal loop also), lipiodol injection, methylene blue injection, digital examination of the rectum, proctoscopic examination and probing of the wound. In all cases the extent of the fistula was ascertained readily and in most of the cases a probe could be inserted through the external opening and could be felt in the lumen of the bowel by the examining finger. Barium enema alone was not very helpful as it was difficult to introduce barium into the small sinus tract in some instances. However, in the lateral view, the barium enema usually showed a posterior tenting of the rectum, and this deformity caused by adherent scar would demonstrate the location of the internal opening. There were three defects which were quite large and would admit the tip of the examining finger in the internal opening.

History

A typical history given by the seven patients up to the time they entered our hospital was that of a young soldier from twenty to thirty years old who was wounded in the buttocks or sacrococcygeal area by gun shot or shrapnel. He was admitted to an aid station, then a surgical evacuation hospital, where treatment was instituted.

Three patients received minimal debridement and abdominal exploration at the surgical or evacuation hospitals. Retroperitoneal hemorrhage was found, injury to the rectum suspected and colostomy performed. All three patients later displayed fecal fistulas through the entrance wounds. Two of the seven patients were treated ideally. The wound of entrance was debrided, and it was apparent that the recum had been perforated. In such cases the rectal wound was closed, the wound packed open loosely and sigmoid colostomy performed. In one soldier the wound was debrided and packed loosely, and in this instance abdominal pain resulted together with signs of abdominal injury. A celiotomy was performed but nothing except retroperitoneal or infraperitoneal hemorrhage was apparent, and the abdomen was closed. A fecal fistula developed within two days in this soldier and it was necessary to make a loop colostomy. Immediate treatment of one soldier who had a large posterior bowel perforation consisted of debridement only and, due to other wounds, shock was present and was treated. On the fourth day after injury he improved and it became evident then that a fecal fistula was present. Colostomy was performed. All seven soldiers were given careful and adequate supportive treatment and were evacuated to the zone of the interior.

On arrival at our hospital all seven patients presented the chronic fistulas described above. Their general condition was good. The abdominal wounds were healed and all colostomies were functiong adequately.

All seven soldiers had had early surgery following the injury and one important principle was carried out in all, i.e., the perirectal space was drained by incision and debridement. In two patients the ideal treatment was instituted initially; that of incising and draining the perirectal space by debridement, then locating the perforation, and closing this opening into the rectum, followed by colostomy. Unfortunately, in both soldiers

---

Inaugural thesis as a member of the Minneapolis Surgical Society.

From the Surgical Service, Billings General Hospital, Fort Benjamin Harrison, Indiana.

chronic fistulas resulted, but I am certain that a great many similar wounds to the rectum were healed in this manner. Croce[1] cited two instances of spontaneous closure of rectal fistula following colostomy alone. There were many other similar instances, no doubt.

It is difficult to determine why such fistulas persist. In all of the soldiers I operated on, the mucosa was everted and markedly adherent to the dense scar tissue which resulted from the healing by secondary intention. In three patients the coccyx had been removed in the original debridement. In two, the badly comminuted coccyx was still present and fixed in the surrounding area by scar tissue, and in the remaining instances the coccyx was undisturbed.

Surgery

Operation was performed in all seven soldiers. The fistulous tracts were excised, the perforations closed and the wounds packed open to permit healing by secondary intention.

Preoperative preparation consisted of irrigating the distal loop, following which all fluid was aspirated. Usual preoperative medications were given, and low spinal anesthesia was used in all instances. A suspension of sulfasuccidine was instilled into the distal loop daily for three or four days preoperatively to decrease the bacterial flora.

At operation almost all of the scar was excised by elliptical excision. The incision was carried toward the midline when the external opening was in the lateral buttocks and the coccyx or fragments of coccyx were removed if present. Very good exposure resulted. The fascia propria was incised transversely in the midline for additional exposure, and by means of blunt dissection through the areolar tissue the proximal rectum was identified as described by Murray.[2] In two patients the perforation was identified at the tip of the fifth sacral vertebra, and in both the everted mucosa was attached firmly to the anterior aspect of the sacrum by osteoperiosteal scar tissue. Removal of the fifth sacral segment by rongeur and stripping of the bowel from the periosteum were necessary in order to mobilize the rectum. In all instances the perforation was identified and the scarified margins excised. The rectal segment was mobilized sufficiently in large perforations to make transverse closure possible, thus preventing undue narrowing of the lumen. With an opening less than one centimeter in diameter, the scarred margin was cleaned and closure made in the direction of least tension, sometimes by purse-string suture. Two rows of inverting interrupted chromic catgut 000 were used in all seven cases. The finger was inserted in the rectum to ascertain a complete closure. Sulfathiazole powder was dusted into the wound and a boric ointment-laden gauze was packed lightly into the defect. A few deep interrupted silk sutures were placed in the lateral extremes of the incision in order to close some of the dead space, but such merely diminished the size and extent of the wound which was to heal by secondary intention.

Postoperative Care

The packs were removed within twenty-four hours and a light cradle was applied to keep the wound dry. Sulfathiazole again was dusted into the depth of the wound and the cavity packed lightly with dry gauze. The wound was dressed daily until healed in three to five weeks. Two or three days after operation all patients were permitted to be up and about the ward. All wounds healed solidly except one which broke down on the seventh day. In this patient the spur of the colostomy was below the skin surface and feces entered the distal loop. I believe this was the main factor in the recurrence, because, after reconstruction of the colostomy and adequately diverting the fecal stream, the fecal fistula was again operated on in the above described manner and healed completely.

In all these soldiers the colostomies were closed while I was still in the army, and there were no recurrences. The most recent colostomy closure was followed for only three weeks. At that time the patient was having normal bowel movements, and the posterior wound was well healed.

Discussion

Perforation of the rectum must be suspected in instances of penetrating injury to the perineal, sacrococcygeal region, or buttocks. Usually a perforation can be seen by proctoscopy or identified on digital examination. If much blood is seen in the rectum, bowel damage usually is present. With bleeding from the rectum and lower abdominal pain present, exploratory operation is indicated if condition of the patient permits. Any injury to the colon above the peritoneal reflection can be repaired and, if retroperitoneal injury is suspected by evidence of hemorrhage in the retroperitoneal space, exclusion colostomy may be performed. Following this procedure, it is important to debride the wound of entrance and adequately drain the perirectal space. If a perforation is seen it should be sutured. If no perforation is seen, the space should be drained, nevertheless, to guard against possible later perforation which may occur because of infarction or contusion of the bowel wall. The colostomy will control the sepsis by eliminating gross contamination and reducing the intraluminal pressure. In addition the incidence of secondary hemorrhage and even perforation of the bowel may be reduced by colostomy. A few cases reported in the literature with perforation of the rectum have had the above ideal treatment, yet fecal fistula has resulted. This may be accounted for by (1) inadequate closure of the perforation, (2) not inverting the mucous membrane and approximating the serosal surfaces of the bowel, (3) the presence of too much infection, (4) a colostomy which does not completely divert the fecal stream or (5) inadequate blood supply as a result of the injury. When the bowel wall is everted and adherent to surrounding structures by scar, there is little chance of the fistulas closing. Many fistulas will heal by conservative means, and some will heal intermittently, only to break down later.

In patients who develop chronic fistulas in spite of the above program, another operation should be performed.

After exposing the area adequately the bowel segment is mobilized sufficiently to close the perforation without tension and the wound allowed to heal by secondary intention.

It is fairly well established that the majority of fecal fistulas of the abdominal colon will close and heal spontaneously, providing the lumen of the bowel is adequate to permit the passage of feces in this area. Further, fistulas from the infraperitoneal colon secondary to operation for low-lying carcinoma with low resection of the rectum usually will heal spontaneously. But with chronic fistulas herein discussed there is little or no chance of spontaneous healing because of trauma, scar tissue, poor blood supply and absence of peritoneum, and surgical repair is certainly indicated.

Summary

Seven soldiers were operated upon for chronic posterior fecal fistula which communicated with the infraperitoneal portion of the rectum following injury by shrapnel and gun shot.

All patients had been operated upon in overseas installations. The wounds of entrance had been debrided and colostomies performed.

There was no evidence of osteomyelitis of the coccyx or sacrum present in any of these cases, in spite of the persistence of mucopurulent and fecal drainage from the fistulas.

The seven patients were treated in a standard manner. The fistulous tract including the surrounding scar tissue down to the bowel wall was excised. The rectum was mobilized adequately, margins of the perforations freshened, and the perforation closed by two rows of fine chromic catgut suture inverting the bowel wall. The wounds were packed lightly with gauze and allowed to granulate in.

Wounds healed readily without complications in six instances and the colostomy was closed later without recurrence of the fistulas.

One patient failed to heal. An inadequate colostomy was reconstructed so that the fecal stream was diverted completely. A further operation was successful and the colostomy was closed later.

Discussion

Dr. Wallace I. Nelson: Allow me to insert a few words about prophylaxis. Now that the war is over it is a little late to prevent these complications in battle casualties, but the principles hold for injuries in civilian life. In studying a large number of these patients with colostomies returning from overseas, I found that a number were not properly defunctioning the distal loop. There were also a large number of patients with wounds of the rectum who merely had a colostomy established but did not have the pararectal space drained until an abscess had formed. As a matter of prophylaxis, I think that the establishment of a truly defunctioning colostomy and the early drainage of the pararectal space would prevent some of the chronic fistulas.

Dr. John R. Paine: I would like to point out one other thing. Doctor Tenner's selection of these cases represents a group of patients which presented as many difficulties as any type of wound which medical officers saw. I think that type of wound, if one excludes the thoraco-abdominal wounds, had about as high a mortality as any in the major categories of wounds. In such cases it was found best by experience to operate on the pelvis first and the abdomen last. This was largely due to the matter of shock occurring with shifting the position of the patient. Frequently, he had to be turned over on the abdomen in the Kraske position to have pelvic surgery done and withstood the shock much more poorly than if the pelvic surgery had been done first.

PULMONARY DECORTICATION FOR INFECTED ORGANIZED HEMOTHORAX

Report of a Case

By H. P. HARPER, M.D.† (By Invitation)
Minneapolis, Minnesota

Pulmonary decortication was described originally in 1893 by Fowler,[4] who advocated the procedure in the treatment of chronic empyema. For various reasons the operation was not widely accepted until World War II. Decortication carried out early in the course of an empyema usually resulted in recurrent or spreading infection. Postponement of the procedure until the empyema cavity became relatively sterile resulted in overmaturity of the fibrin wall which made stripping impractical or impossible. In the treatment of organized hemothoraces in the war wounded, the advent of effective chemotherapeutic agents and antibiotics was very timely. By their use, septic complications were reduced to a minimum and the time of surgical intervention became elective. In these cases, pulmonary decortication attained such notable success that the procedure possibly should be re-evaluated as to its place in the treatment of empyema.

It appears that even in experienced hands at least 5 per cent of all significant acute hemothoraces result in either empyema or a chronic organizing phase in spite of various methods of therapeutic management.[2,6] The chronic phase is characterized by the development of an intrapleural, space-occupying, fibrous envelope usually filled with a viscous, plasma-like liquid, containing fibrin shreds and the debris of degenerated red blood cells. The exact pathogenesis and mechanism of this change are not entirely clear but, at least under certain circumstances, whole blood in the pleural cavity apparently lays down its fibrin content on all pleural surfaces bounding it. The constant thrashing movements of the diaphragm, mediastinal wall, and thoracic wall possibly stimulate this fibrin deposit on the moving parts in much the same manner as occurs when whole blood is stirred with a spatula.[3] Simultaneously, red cell degeneration begins at the center of the hematoma in the defibrinated blood, which is much diluted by effusion from the easily irritated pleura. Early in the course of events, while fibrin is still being laid down about the periphery of the hematoma, active fibroplasia and angioplasia begin in the fixed fibrin nearest the pleura.[1] This proliferative process proceeds from the pleura towards the center of the hematoma and, in about three weeks,

†Surgical resident, Minneapolis Veterans Hospital.

results in the formation of adult fibrous tissue in those portions nearest the pleura. This organizing fibrous wall has been given the name of "peel." If undisturbed surgically or otherwise, the peel and the underlying pleura are said to attain cellular intimacy in about eight weeks.[1,3]

A markedly decreased vital capacity produced by the persistent space-occupying lesion is the most pronounced physiological disturbance of an uncomplicated organizing hemothorax. The immobilization of the diphragm and mediastinum further disturb normal physiology and may give rise to symptoms. The collapsed and partially atelectatic lung is very prone to abscess formation, bronchiectasis, or pneumonitis. The nutrient-rich fluid contained within the peel is also particularly subject to infection and to the development of complicating empyema.

Organized hemothorax does not produce any particularly diagnostic symptom complex. Its development in carefully followed chest injuries is usually obvious, but many cases are asymptomatic until supervening infection precipitates signs. As has been pointed out frequently, the history of significant chest trauma may be misleading or difficult to elicit. Nonspecific symptoms such as chest pain, dry cough, dyspnea, malaise, anemia or weight loss may direct attention to the chest. Hemoptysis, foul sputum, chills, and fever usually are the results of complications, but often provide a lead. The history of even insignificant chest trauma; the clinical and roentgenological demonstration of an immobile, persistent, space-occupying, intrapleural mass; and the aspiration of blood or degenerated products of blood from the mass usually suggest the diagnosis.

Since atelectatic lung and the degenerated center of an organizing hemothorax are both very prone to develop infection, the primary aim of surgery must be the complete re-expansion of the lung with obliteration of all dead space. In cases where more than 50 per cent of a pleural cavity is involved, this can be accomplished best by evacuation of the liquid contents of the mass and removal of that portion of the peel actually constricting the lung. Normal respiratory physiology may be re-established further by removing the constricting peel from the diaphragm. Since the peel develops adult fibrous tissue in its deep layers after three weeks and does not attain cellular intimacy with the underlying pleura until eight weeks, this is the ideal period for decortication. If decortication is attempted too early, the peel will not have attained sufficient intrinsic strength to allow easy surgical manipulation. If allowed to mature too long, the peel can be separated from the underlying pleura only with difficulty, and much capillary bleeding results. In this over-mature stage decortication may result in such extensive tearing of pleura and lung tissue that Ransohoff's discission operation[5] may be the procedure of choice.

By proper use of effective chemotherapeutic agents and antibiotics, pulmonary decortication may be carried out successfully even in the presence of infection within the hematoma. Burford, et al.[1] report nineteen cures out of twenty-five cases of infected organized hemothorax treated by decortication. The remaining six developed small basal empyemas requiring further minor surgery. From this and other reports of comparable success in the treatment of this special type of empyema, it is interesting to speculate that, with the development of further improved bacteriostatic and bacteriocidal agents, pulmonary decortication may become the treatment of choice in the management of most empyemas.

Recently at the Minneapolis Veterans Hospital a pulmonary decortication was performed successfully for massive infected organized hemothorax. As a reminder that this condition occurs in civilan life and as evidence of the effectiveness of the procedure in spite of existing infection, the case is reported in some detail.

Case Report

A railroad lunch concession clerk, aged fifty-five, was admitted to the Minneapolis Veterans hospital, August 6, 1946, with a history of having sustained minor lacerations of the right elbow, the right knee, the frontal scalp and the right anterior chest the night of June 24, 1946, when he tripped over a railroad tie while returning home from work. The lacerations were sutured and dressed by his family physician who was consulted the same night. There were no significant symptoms, and the patient continued his usual work for about two weeks thereafter.

On the night of July 8, 1946, the patient experienced a sudden, rather oppressive dyspnea when he arose from bed to urinate. Severe sharp pains in the right lower chest began at the same time. The pain was most marked posteriorly and was made worse by deep respirations. There was no cough, sputum, or hemoptysis. Weakness, malaise and anorexia were progressive, and the patient was unable to work. The dyspnea persisted and was aggravated by any type of exertion. The right chest pain gradually decreased in severity and disappeared completely by the end of the month.

A dull aching pain and sensation of numbness in the right shoulder appeared, August 3, 1946. This pain seemed to radiate down the right arm to the ulnar side of the hand. The patient finally decided to seek further medical advice because of this new symptom and because of his poor general health, including a weight loss of 20 to 25 pounds.

The past history, family history, and history by systems were noncontributory.

The physical examination on admission revealed a fairly well developed but rather emaciated white man displaying moderate but obvious dyspnea. His temperature was 101 degree Fahrenheit. The pulse was 120 per minute. Respirations were counted at 24 per minute. The blood pressure, 110 systolic and 70 diastolic in millimeters of mercury. The general physical examination was essentially negative except for the chest which showed almost complete lack of respiratory excursion on the right. There was percussion dullness with total absence of fremitus and breath sounds on the right side below the level of the third rib anteriorly. The heart was normal in size to percussion, and no murmurs or irregularities of rhythm were detected.

Admission laboratory tests showed a hemoglobin of 8.6 Gm. and erythrocyte count of 3,260,000 for each cubic millimeter of blood with hyperchromasia, anisocytosis, and poikilocytosis on smear. The leukocyte count was 8,400 with 76 per cent polymorphonuclears, 23 per cent lymphocytes, and 1 per cent monocytes. The sedimentation rate was 115 millimeters in one hour. Urinalysis, blood serology, and sputum studies for acid-fast

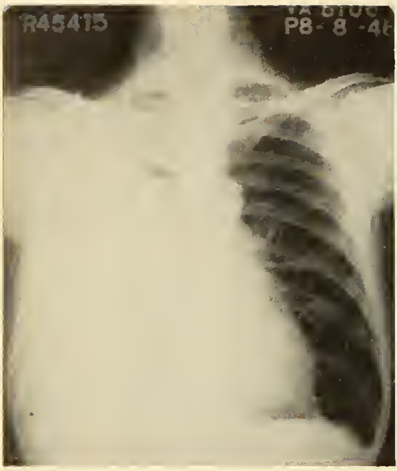

Fig. 1. Chest x-ray examination on admission shows massive right hemothorax.

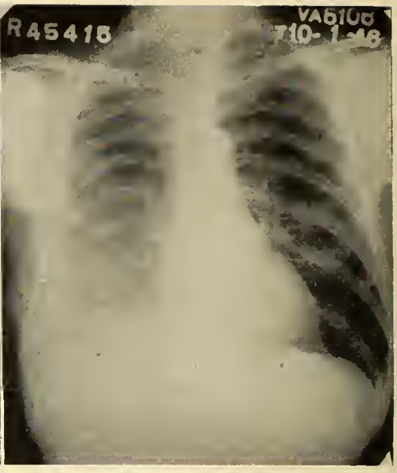

Fig. 3. Chest x-ray examination at the time of postoperative follow-up shows some residual thickened pleura in the right lower thoracic cavity.

bacilli were negative. Blood chemistry studies were all normal.

X-ray examination on admission (Fig. 1) demonstrated fluid obscuring the entire right half of the thorax except for a narrow triangular strip of air-containing lung ascending from the right hilum to the apex.

The diagnosis on admission was "pleural effusion, right thorax, etiology undetermined," and the patient was accepted on the medical service for detailed study and treatment.

A thoracentesis of the right chest was performed August 8, 1946, and 500 cubic centimeters of syrupy dark red fluid were aspirated. X-ray examination immediately thereafter showed no significant change other than the appearance of bubbles of air overlying multiple fluid levels. The roentgenologist's diagnosis was multilocular, encapsulated empyema. Laboratory examination of the aspirated fluid showed a protein of 3.7 grams for each 100 cubic centimeters, a leukocyte count of 18,000 for each cubic millimeter of fluid, and an erythrocyte count of 500,000 for each cubic millimeter. No tumor cells or acid-fast bacilli were found. Culture of the fluid was positive for hemolytic staphylococcus aureus.

General supportive medical management was carried out, and the patient was given two blood transfusions of 500 cubic centimeters each. He improved somewhat clinically but continued to follow a febrile course with a daily fever of 100° to 101° F. in spite of the administration of 40,000 units of penicillin parenterally every four hours. On August 13, 1946, a second thoracentesis was performed and 350 cubic centimeters of fluid identical with that of the first aspiration were removed. Re-examination of the blood on August 14 showed that the hemoglobin had risen to 14.6 Gm. and the erythrocyte count to 4,250,000.

August 15, 1946, the patient was seen by the surgical service in consultation. The diagnosis of an infected organized hemothorax seemed likely but a primary malignancy of the pleura could not be excluded because of the patient's age, the insignificant history of trauma, and the lag between apparent trauma and the onset of symptoms. It was felt that in either case an exploration of the right chest was indicated.

Operative Procedure.—On August 16, 1946, the right thorax was opened after wide subperiosteal costectomy of the seventh rib under intratracheal cyclopropane anesthesia. About 2,000 cubic centimeters of syrupy brown fluid containing many large soft fragments of fibrin were removed and the typical firm, smooth peel of an organized hemothorax was revealed. Superiorly slight transmission of the respiratory movements from the constricted atelectatic lung could be felt. Palpation inferiorly showed a diaphragm completely immobilized by the fibrous peel. No evidence of neoplasm was detected.

That portion of the peel in contact with the lung superiorly was then removed by careful blunt dissection. A similar removal of the peel from the diaphragm resulted in immediate resumption of normal respiratory excursions. The lung was freed from minor adhesions of the upper mediastinum and then was expanded to normal size by positive pressure applied through the intratracheal tube. Fenestrated catheters were placed in the lower portions of the thoracic cavity anteriorly and posteriorly through trocar punctures and the operative incision was closed tightly in layers without drainage using fine interrupted silk sutures. 100,000 units of penicillin in 400 cubic centimeters of saline were instilled through the posterior catheter and, after maximum expansion of the lung had been assured, both catheters were clamped. The tracheo-bronchial tree was aspirated per bronchoscope and the patient was returned to his room where a constant negative pressure of 12 to 14 centimeters of water was applied immediately to the anterior catheter by means of a Stedman pump setup. The patient remained in the Trendelenburg position until his blood pressure was stable and he had fully recovered from anesthesia. He was then placed in semi-Fowler's position. After a period of six hours, in which to allow residual penicillin to be effective, the posterior catheter was unclamped and likewise attached to the suction apparatus. Chest radiograph taken directly after surgery showed that the right lung had been re-expanded to about 75 per cent of normal (Fig. 2).

Postoperatively, particular attention was directed toward the maintenance of uninterrupted negative pressure within the affected side of the thorax. Twenty cubic centimeters of 250 units for each cubic centimeter of penicillin were injected by needle through the wall of each catheter every four hours to keep them clear. Fluid balance was maintained carefully and protein intake augmented by 45 grams of amino acids intravenously for each day. Forty thousand units of penicillin were administered parenterally every three hours, and pain was controlled by the administration of 50 to 75 milligram doses of demerol.

Examination of the fragments of peel removed at operation showed them to be firm and fibrous with an average thickness of 5 mm. Microscopically (Fig. 4), the surface toward the center of the hematoma was made up of many young fibroblasts and newly developing capillaries. The surface toward the pleura was densely fibrous and resembled scar tissue. The intermediate area showed gradual transition between these extremes.

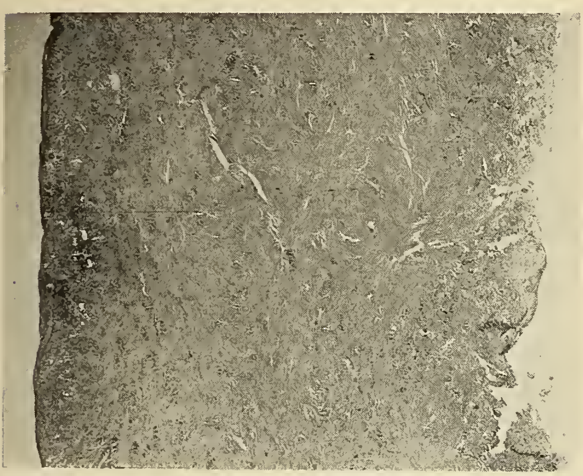

Fig. 4. Microphotograph of the peel removed at operation. On the right is the mature fibrotic peripheral portion. On the left is the immature organizing central portion showing active fibroplasia and abundant newly developing capillaries.

On the third postoperative day the anterior catheter was removed, and the patient was allowed to sit on the side of his bed the following morning. On the fifth day the posterior catheter was removed, and the patient was allowed up in a wheel chair. Convalescence was steady, and by the ninth postoperative day he was fully ambulatory and afebrile.

On August 27, 1946, the eleventh postoperative day, a fever of 100.6° developed, and examination revealed a phlebothrombosis of the lower extremities extending up to the popliteal spaces bilaterally. Anticoagulant therapy consisting of oral dicumerol and continuous intravenous heparin was started at once. The blood prothrombin concentration decreased enough in forty-eight hours to permit discontinuance of heparin. Administration of oral dicumerol was continued for a total of 10 days. The remaining convalescence was uneventful and the patient was discharged from the hospital, September 10, 1946.

On November 1, 1946, the patient returned to the surgical outpatient section for postoperative checkup. Physical examination at that time revealed nothing abnormal except minimal tenderness in the operative scar. The patient had gained about 14 pounds in weight and felt very well. X-ray examination of the chest revealed some residual thickened pleura at the right base but was otherwise normal (Fig. 3).

Summary

The pathogenesis of organized hemothorax is discussed briefly. The case of a patient with an infected organized hemothorax who became symptomatic two weeks after apparent insignificant chest trauma is reported. The technique of the decortication operation and the postoperative management of the reported case are presented in some detail.

Discussion

Dr. John R. Paine: Doctor Harper's case is the first one of the kind which has come to my attention in civil practice. It is still difficult for me to believe that the trauma this man says he suffered caused the hemorrhage in his chest, but we have been able to find no other cause. Those who have had no experience in decortication of the lung have missed some of the pleasures of surgery. There are certain things that give us pleasure. A surgeon derives real satisfaction, after going into the chest, scooping out cups of blood and not being able to find the lung, in taking the peel off and seeing the lung expand under his hand so that when he has finished the lung fills the chest cavity completely.

We had a striking experience during the war treating organized hemothorax. The American way of treatment in most of these cases was as Doctor Harper has indicated. The British never did become convinced of the merits of this operation. They stuck to the conservative idea of repeated aspirations. That isn't entirely true but the general British plan was not to do so radical an operation. They preferred to aspirate a few ounces of fluid this week and then next week take a few more ounces. In the majority of cases treated this way, the patient regained a large percentage of his vital capacity, but I do not believe the recovery was as complete as when the patient is operated on and the peel removed. I am sure the time of recovery is much shorter when the patient is treated by the method described by Doctor Harper.

CRITERIA FOR CHOLEDOCHOSTOMY TUBE REMOVAL

R. W. UTENDORFER, M.D.†

Minneapolis, Minnesota

The general policy of surgeons in this area has been to insert some type of choledochostomy tube whenever the common bile duct has been opened during a surgical procedure. It is important, therefore, to establish definite critieria for determination of the optimal time for removal of such a tube.

At the Minneapolis Veterans hospital we employ the three criteria which have been suggested previously by Bergh.[3]

> (1) cholangiographic evidence that the biliary tree is structurally normal, that no filling defects suggestive of stone are present, and that the contrast medium empties readily into the duodenum; (2) direct evidence that the sphinc-

---

ter resistance is normal and that the sphincter is not irritable; (3) subjective comfort of the patient, and lack of drainage around the tube when the catheter is clamped.

Before a choledochostomy tube may be removed it is essential that the patient be comfortable during periods when the tube is clamped. However, this simple clinical test in itself is not sufficient, for it is well known that stones may be present in the duct without obstructing bile flow and without producing symptoms. Likewise, we have demonstrated that the patient with an irritable sphincter of Oddi may, at times, tolerate closure of the choledochostomy tube without discomfort.

Cholangiograms are made in all cases in which a patient has a tube draining the common bile duct. A satisfactory cholangiogram is best obtained by the use of a nontoxic contrast medium having a watery consistency, miscible with bile. The hepatic ducts and the common duct should be filled, and the ease with which the contrast medium enters the duodenum should be observed. Cholangiograms are most important in the recognition of calculi or other duct obstructions, but also may reveal the presence of hepatic abscesses, and possibly spasm of the sphincter of Oddi, or stricture of the duct due to inflammatory reaction. In this connection, Royer[15] states that he is able to distinguish spasm from stricture on the basis that spasm gives eccentric narrowing of the duct shadow, while concentric narrowing is a finding in true stricture. Important as cholangiography is, it still leaves information to be desired concerning the condition of the sphincter of Oddi, whether it is in spasm, whether it is irritable and may be stimulated to contract in abnormal spasm, or whether it has normal tone. In order to evaluate this with any degree of accuracy it is necessary to conduct direct tests of the resistance of the sphincter of Oddi.

Although the technique of this test is simple, it is not yet in general use, and may therefore be described briefly. The apparatus required consists of an infusion flask connected to the open end of the choledochostomy tube by rubber tubing, incorporating a Murphy drip bulb in the system so that flow may be observed. The apparatus is sterilized, filled with saline solution, and air is evacuated from the system, save for the small air gap in the Murphy drip bulb. The flask is suspended from a standard, and arranged so that it may be elevated and lowered at will, thereby varying the pressure of the column of fluid in the system. Readings are taken directly on a centimeter scale suspended from the standard, and adjusted so that the zero point is placed at the estimated level of the common bile duct.

In carrying out the test, the infusion flask is elevated, then lowered to the point at which saline solution fails to run through the tubing. When this point is reached, the column of solution is supported without any flow in either direction, and the drop suspended in the Murphy bulb moves with the respiration of the patient. Elevation of the flask above this point allows saline solution to flow into the biliary tract, as evidenced by dripping solution through the Murphy drip bulb, and lowering the flask beyond this point causes reflux of fluid back into the infusion system. The level at which the column of saline solution is suspended without flow in either direction is taken as a measurement of the sphincter resistance. That this test is fairly delicate, in spite of the simplicity of the apparatus, is demonstrated by the marked changes produced by induced spasm, as when morphine is administered, or the flask suddenly elevated. Whenever practicable, the test is performed in the morning, after withholding breakfast, or at other times of the day, after a fasting period of four to eight hours, since it has been shown that ingestion of food lowers sphincter resistance—fatty foods having a marked effect, with less response to protein, and no effect after ingestion of carbohydrate.[4] The patient should not have received opiates prior to the test, since morphine, codein and related drugs produced spasm of the sphincter.[3]

By this technique, the resistance offered by the sphincter of Oddi has a normal range of 9 to 23 centimeters of water, with the ideal normal being 13 to 15 centimeters. Spasm of the sphincter may produce readings indicating a resistance of 30 to 40 centimeters of water, or more, and in these patients the resistance readings are usually more fluctuant than in normals. Irritability of the sphincter thus demonstrated is probably more commonly associated with organic pathologic condition such as an inflammatory process, or irritation caused by stone; but purely functional derangement (biliary dyskinesia or biliary dyssenergia) may also produce spasm.

From this, it is seen that by sphincter resistance tests we are able to tell, with a fair degree of accuracy, the condition of the sphincter of Oddi, in so far as tone and spasm are concerned, but this test gives no information as to the presence of stone or growth not causing obstruction, unless there be an associated irritability of the sphincter, as is often the case.

It has been the practice at the Minneapolis Veterans Hospital to judge the time for removal of the choledochostomy tube on the basis of these three criteria. If the patient tolerates clamping of the tube for twelve hours without discomfort, if the cholangiogram is normal, and if the sphincter is not irritable and the resistance is normal, the tube may be removed. In the usual uncomplicated case the cholangiogram may be done on the seventh to ninth day postoperatively, and the sphincter resistance test may be done the following day. The choledochostomy tube may, thefefore, be removed in eight to ten days in the event of a normal response.

In the presence of an irritable sphincter, however, the choledochostomy tube should be left in place for longer periods of time. Prolonged decompression of the ducts by means of external drainage permits the sphincter to return gradually to normal. We have seen a number of cases in which this has occurred. The time required for the return of the sphincter to normal may be from several weeks to several months. However, if the still irritable, the patient is very likely to suffer recurrence of pain which may resemble biliary colic, or we have seen no patient in whom the criteria for re- may be a vague epigastric distress. In contrast to this, choledochostomy tube is removed while the sphincter is moval of choledochostomy tubes have been satisfied who has had postcholecystectomy pain.

We may conclude, therefore, that we have available three valuable criteria for judging the time when a choledochostomy tube may be removed, each of these having its own particular advantages and limitations. In recapitulation, clamping the tube is a clinical test of limited value, which gives little information as to the structural or physiological status of the duct system. Cholangiograms give a picture of the anatomical condition of the biliary ducts, but give little information concerning the condition of the sphincter. Since this condition of the sphincter is such an important consideration, direct measurement of the resistance of the sphincter of Oddi should be carried out. No single test furnishes sufficient information concerning the postoperative morphology and physiology of the biliary duct system, but by employing all three criteria we are able to gain valuable knowledge as to the condition of the ducts, the presence or absence of stones, the condition of the sphincter, and the tolerance of the patient to the existing conditions. The optimal time for removal of a choledochostomy tube may, therefore, be determined accurately by the use of these criteria.

Discussion

Dr. George Bergh: There is little to add to what Doctor Utendorfer has said. He has covered the subject very well from our point of view. The criteria have been of real value to us, and we employ them routinely.

Dr. J. M. Hayes: I am wondering whether there are any statistics as to what was the average time for removing the tube.

Dr. R. W. Utendorfer: In the normal case, from eight to ten days.

Dr. Carl Rice: I would like to ask Doctor Utendorfer and Doctor Bergh whether there are medications which will relieve the spasm of the sphincter? I notice morphine did not.

Dr. R. W. Utendorfer: The only drugs that have been found to be very effective on the sphincter are amyl nitrite and, to a lesser extent, nitroglycerine. There are some cases in which spasm of the sphincter is not relieved by amyl nitrite. Atropine and some of the usual spasmolytic agents have no effect. We are testing some of the newer ones at present, but cannot tell about them yet.

MASSIVE GASTRIC HEMORRHAGE DUE TO HEMORRHAGIC GASTRITIS NECESSITATING GASTRIC RESECTION

Case Report

G. H. HALL, M.D.†
Minneapolis, Minnesota

Surgical arrest of massive gastrointestinal hemorrhage continues to offer problems of major importance. This is particularly true when the vomiting of blood or the passage of large, bloody, loose and frequent stools occurs in a patient who presents practically no other symptoms or findings. Consideration of possible causes of the bleeding then becomes a matter of considerable concern.

Reports from most of the larger clinics indicate that ulcers of the stomach or duodenum are responsible for 90 per cent of upper gastrointestinal tract hemorrhages. The next most common cause, bleeding from esophageal varices, secondary to cirrhosis of the liver, has a reported incidence of from 2 to 5 per cent. Other less frequent causes of hematemesis and melena include carcinoma of the stomach or duodenum, benign tumors of the stomach, injuries to the stomach, blood dyscrasias, and ulceration in a Meckel's diverticulum.

Another possible source of massive bleeding from the upper gastro-intestinal tract, and one which has received little emphasis, is hemorrhagic gastritis. Bockus reports that in about one-fourth of the cases of massive hemorrhage into the upper gastrointestinal tract, roentgen study performed after the emergency is over fails to reveal an ulcer or other gastroduodenal lesion. Meyer and Steigmann[2] state that negative x-ray findings are reported in from 30 to 50 per cent of patients who have had gastric hemorrhage. Pathologists not infrequently have been unable to demonstrate at autopsy the source of bleeding in patients who have seemingly died of massive upper gastrointestinal hemorrhage. It should be recalled that post-mortem antolysis of the mucous membrane of the stomach occurs soon after death.

Examination of the stomach with the gastroscope has enabled visualization of areas of gastritis from which oozing of blood occurs and actual superficial ulcerations have been noted. It is not at all unlikely that a high percentage of the 25 to 50 per cent of patients who have negative x-ray findings after hemorrhage has subsided bleed from such lesions. As yet, the frequency of gastritis as a cause of massive upper gastrointestinal hemorrhage has not been determined. That it can occur and that it can cause massive bleeding has been emphasized to the staff at the Minneapolis Veterans hospital by experience with the following case.

Case History

The patient, a thirty-two-year-old veteran of World War II, was admitted to the medical service of the hospital on September 15, 1946. His presenting com-

---

†Surgical resident, Minneapolis Veterans Hospital.

plaints were severe weakness and dizziness following the passage of large black liquid stools beginning three days prior to admission.

The patient's army career began in March, 1944, when he was assigned to the infantry. He had had no complaints referable to the gastrointestinal system until January, 1945, when he noticed a bloody stool. There were no other symptoms at that time. He was hospitalized in an army general hospital, where he apparently was studied thoroughly. A barium x-ray examination of the stomach was made, stools were examined, and he was put on various diets. After having been hospitalized for about a month, he was discharged to duty, but transferred from the infantry to the air corps, where he assumed the duties of a truck mechanic. He was told only that he had a "nervous stomach." He experienced no further appreciable difficulty during his remaining army service. The patient stated that he drank only very moderately and smoked about one package of cigarettes a day.

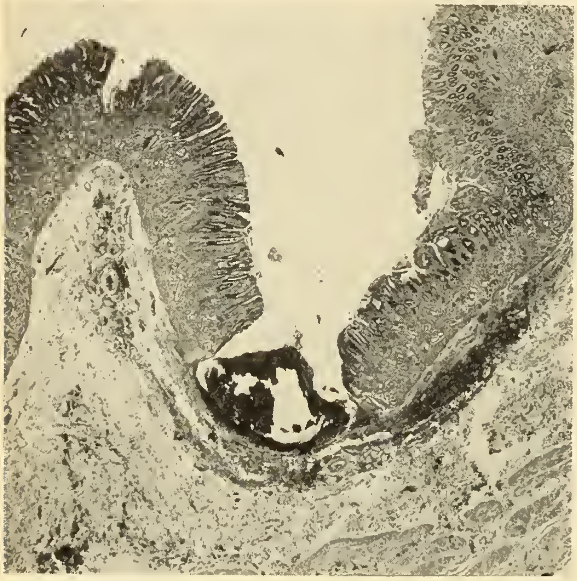

Fig. 1. Section taken through the linear lesion in the mucosa.

About one month prior to admission, he began to experience a dull aching distress, which he described as "bloating." This would begin in both flanks and gradually extend into the epigastrium, where it would remain. This distress usually occurred about one-half hour after meals and would be relieved somewhat by belching or by the ingestion of alkalis.

On the evening of September 12, three days prior to admission, he had a large bowel movement, consisting entirely of black liquid. Following this, he experienced severe cramping pains in the lower abdomen, which were relieved by two additional passages of black liquid. He became weak and experienced dizziness on walking or standing. On the following day, he continued to feel weak and dizzy. No nausea nor vomiting was experienced, however, and he was able to eat normally. The next day, defecation again produced a black liquid stool, and on September 15, another black liquid stool was passed. His family physician then was called and that same day he was sent to the hospital, where he was admitted with a tentative diagnosis of bleeding peptic ulcer.

Examination on admission revealed an unusually tall, slender, red-haired male. Although he was 6 feet 6 inches tall, the patient weighed only 140 pounds. There was noted a generalized, moderately severe pallor of the skin and mucous membranes. He appeared to be nervous and apprehensive. The temperature on admission was 99.2 Fahrenheit, the pulse rate 120 per minute and the blood pressure was 112 systolic and 60 diastolic in millimeters of mercury. The heart and lungs were normal to percussion and auscultation. The abdomen was flat and soft. No masses were palpated and no tenderness found. The liver and spleen were not enlarged. No other physical abnormalities were noted.

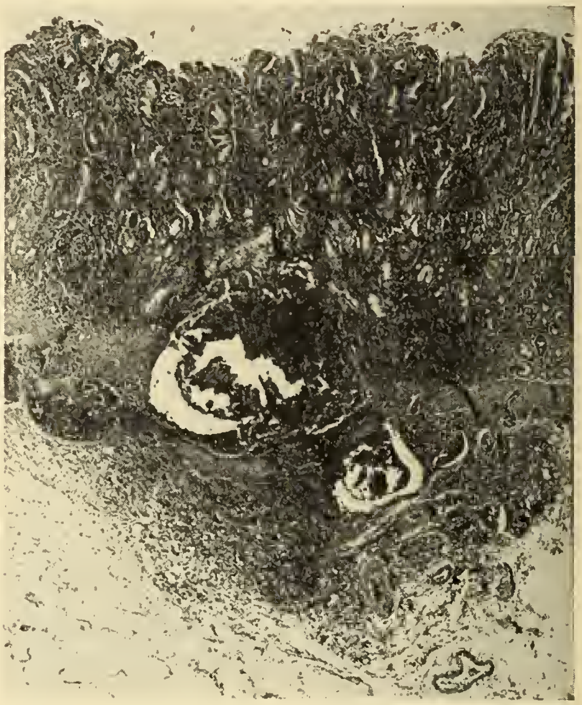

Fig. 2. Section through one of the smaller hemorrhagic areas. Note the large number of erythrocytes in the region of the muscularis mucosae, with break-through into the mucous membrane.

The hemoglobin on admission was 4.9 grams (31 per cent) and the red blood cell count was 1.6 million. The white blood cell count ranged from 6,000 to 11,000 and differential counts were within normal limits. The bleeding time was two and one-half minutes, the clotting time was six minutes, and the prothrombin time was thirteen seconds as compared with a normal control of thirteen seconds. Study of the blood morphology revealed findings consistent with a secondary anemia. Urinalyses showed no albumin, sugar, nor abnormal sediment, and specific gravities ranged from 1.009 to 1.024. Stool examinations consistently showed a four plus guaiac test for occult blood.

On admission to the medical service, the patient was placed on a regimen of strict bed rest and was given morphine. A nasal tube was introduced into the stomach and he was given a continuous drip of high caloric, high protein liquid diet night and day. Amphogel, ascorbic acid and vitamin K were added. Atropine sulphate, grains 1/100, was given every six hours. Daily transfusions of 500 cubic centimeters whole citrated blood were administrated by slow intravenous drip. After three days of this treatment, the patient felt much improved, the hemoglobin had risen to 9.7 grams (62 per cent) and the red blood cell count to 3.1 million. Nasal tube feedings were discontinued and hourly feedings of milk and cream alternating with amphogel were substituted. The first bowel movement during hospitalization occurred two days after admission, however, and was definitely tarry.

Five days after admission, the patient suddenly became faint and vomited 900 cubic centimeters of bright red blood. 1,000 cubic centimeters of whole blood were given during the night, and the hemoglobin and red blood cell count the following morning remained at about the previous level. The hematocrit was 29 per cent. The blood pressure, which was checked hourly, remained at around 110 systolic and 70 diastolic, and the pulse at about 100 per minute. Surgical consultation was requested the following morning. Because the patient had not been in true shock and because the source of bleeding had not been determined, the decision was made to continue medical management in the hope that bleeding would subside so that a barium study of the upper gastrointestinal tract might enable localization of the bleeding area. Gastroscopy was considered, but deemed unwise. It was thought, however, that if further massive hemorrhage should occur, immediate surgical intervention should be undertaken.

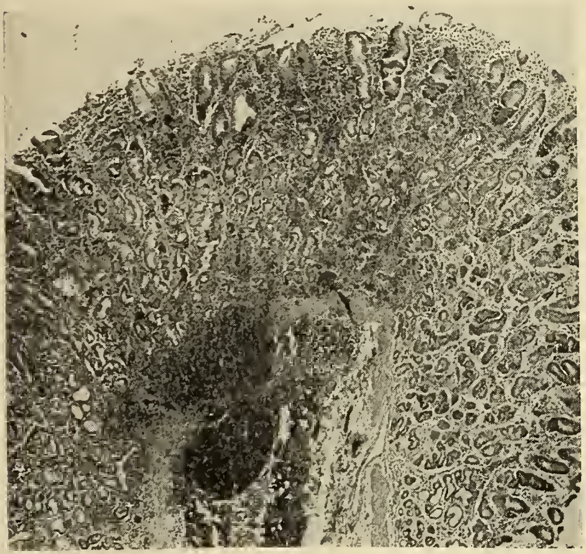

Fig. 3. Another section through a small hemorrhagic area. Erythrocytes have not broken through to any great extent.

The previously outlined medical management was continued. One definitely tarry stool was obtained by enema, but additional stools were reported to be lighter in color. Ten days following the episode of hematemesis, the medical resident was called at 3:30 a.m. because the blood pressure had dropped to 86 systolic and 55 diastolic. One unit of plasma followed by 500 cubic centimeters of whole blood restored the pressure to normal. It was found, however, that the hemoglobin had dropped to 6.7 grams (43 per cent) and the red blood cell count to 2 million for each cubic millimeter of blood in spite of the transfusion. Since hemorrhage appeared to be continuing despite eighteen days of active medical management, preparation for surgery was deemed advisable. Because it was feared that barium x-ray study or gastroscopy might cause further bleeding and because probabilities were in favor of a bleeding gastric, or duodenal ulcer, these diagnostic aids seemed contraindicated. The patient was given sufficient blood to raise the hemoglobin to 15.4 grams (98 per cent) and the red blood cell count to 4.5 million by continuous slow drip and laparotomy was performed nineteen days after admission. He had received a total of 7,500 c.c. of whole blood prior to operation.

Under intratracheal cyclopropane plus curare anesthesia, a left subcostal incision was made and the abdomen explored. The stomach was unusually large and elongated, and the stomach wall was edematous, but the serosal surfaces presented no evidence of scarring. The first portion of the duodenum was distended, but there was no deformity or scarring anteriorly and no adherence to the pancreas posteriorly. The small bowel was examined from the ligament of Treitz down to the terminal ileum. No abnormalities were noted except that black liquid, presumed to be blood, could be seen through the serosa beginning high in the jejunum. The colon also contained a large quantity of soft black material. Since no other cause for the hematemesis and melena could be established, it was decided that a small peptic ulcer was the most likely cause and that gastric resection should be done. The pyloric portion of the stomach and about four centimeters of the duodenum distal to the pylorus were first devascularized and the duodenum opened. The mucous membrane appeared to be normal and careful inspection failed to reveal the prescence of a bleeding point. The duodenum then was inverted with a running layer of chromic catgut re-inforced by a second layer of interrupted 0000 silk sutures. The inverted duodenal stump was buried into the capsule of the pancreas.

The greater curvature was devascularized up to and including the lower two vasa brevia and the lesser curvature to the left gastric artery. About 75 per cent of the stomach was removed and a Hofmeister type of short-loop, retrocolic gastro-jejunostomy performed, using the Wangensteen aseptic technique.

Upon opening the resected stomach, the pathologist found no ulcer present. The mucosa of the stomach was thrown into normal appearing rugae except in the pyloric antrum, where it was smoother. On the posterior wall of the fundal portion of the stomach, there was noted a linear defect in the mucosa measuring 2 centimeters in length and up to 3 millimeters in diameter. The defect was shallow, dark red, and presented irregular borders. In addition, other sections showed occasional tiny hemorrhagic foci within or just beneath the mucosa.

Some doubt remained as to the source of the hemorrhage, however, until miscroscopic studies were made. Sections through the linear lesion in the mucosa showed complete dissolution in continuity of the mucous membrane extending into the muscularis mucosa and possibly into the deeper muscle layers. There was a dense infiltration of extravasated blood. Sections through the smaller hemorrhagic areas revealed massive aggregations of erythrocytes, most densely collected in the muscularis mucosa. In some instances, there seemed to be actual necrosis of this muscular layer. There was definite edema between the muscular layers and in the connective tissues. Furthermore, inflammatory cellular exudate, and mild scatterings of eosinophiles, polymorphonuclear cells and lymphocytes, was noted in the vicinity of the lesions. The diagnosis of the pathologist was subacute diffuse gastritis with focal mucosal and submucosal hemorrhages.

The postoperative course was without complication. No further melena or hematemesis occurred, and no more blood transfusions were necessary. Gastric analysis postoperatively proved the patient to be achlorhydric to histamine. Barium radiographic examination revealed no abnormality of the esophagus or residual pouch, and barium passed readily into the small bowel. The patient was seen subsequently one month after surgery. There had been no recurrence of his previous symptoms. He stated at that time that he had been feeling fine, had been eating well, and had gained about 10 pounds in weight.

PRIZE CONTEST ANNOUNCED

The American Association of Obstetricians, Gynecologists and Abdominal Surgeons announces a Foundation prize contest.

Further information may be obtained from Dr. James R. Bloss, secretary, 418 Eleventh Street, Huntington 1, West Virginia.

E. STARR JUDD LECTURE

The fourteenth E. Starr Judd lecture will be given by Dr. I. S. Ravdin, John Rhea Barton Professor of Surgery at the University of Pennsylvania, Tuesday evening, April 15, 1947, at 8:15 in the Auditorium of the Museum of Natural History. Doctor Ravdin's subject is "Changing Concepts in Surgical Care."

The late E. Starr Judd, an alumnus of the Medical School of the University of Minnesota, established this annual lectureship in surgery a few years before his death.

AMERICAN COLLEGE OF CHEST PHYSICIANS

The thirteenth annual meeting of the American College of Chest Physicians is scheduled to be held at the Ambassador Hotel, Atlantic City, New Jersey, June 5 to 8. An interesting scientific program has been planned for this meeting. Prominent speakers from other countries will present papers.

The oral and written examinations for Fellowship will be held on the first day of the meeting, June 5. Applicants for Fellowship in the College who plan to take these examinations should communicate *at once* with the Executive Secretary, American College of Chest Physicians, 500 North Dearborn Street, Chicago 10, Illinois.

The convocation for new Fellows and Life Members of the College will be held on Sunday, June 8. At this time certificates will be awarded to Fellows and Life Members admitted since June, 1946.

AMERICAN SOCIETY FOR THE STUDY OF STERILITY

The third annual convention of the American Society for the Study of Sterility will be held at the Hotel Strand, Atlantic City, New Jersey, on June 7 and 8, 1947, preceding the annual AMA Convention. The general theme of the meetings will be that of attempting to disseminate to the physician treating marital infertility an over-all picture of the latest advances in reproduction. The convention will include original papers, round table discussion, scientific exhibits, and personal demonstrations. Registration for the sessions is open to members of the medical and allied professions.

Additional information may be obtained from the secretary, Dr. John O. Haman, 490 Post Street, San Francisco 2, California.

INDUSTRIAL HEALTH MEETINGS

A conclave of combined professional personnel in industrial health work over the entire nation will take place at the Hotel Statler, Buffalo, N. Y., April 26 through May 4, 1947.

These meetings will represent the 32nd annual gathering of the American Association of Industrial Physicians and Surgeons; the ninth annual conference of the American Conference of Governmental Industrial Hygienists; the eighth annual meeting of the American Industrial Hygiene Association; the fifth annual conference of the American Association of Industrial Nurses, and the fourth annual meeting of the American Association of Industrial Dentists.

The sessions will be replete with many new subjects of interest, including among others, round table discussions for chemists, engineers, physicians and nurses; a symposium on new problems in the developments of industrial hygiene; a discussion of state codes and industrial hygiene administration; conferences on environmental control, on particle size, and analytical procedures; clinics on fractures and traumatic surgery, including a symposium on back problems; hazards incident to the use of the atomic bomb; reports on the Bikini experiments with motion pictures; tracer chemistry in toxicological research and experience with range finding tests; progress in the teaching of industrial medicine in Amer-

indications for "smoothage"

"smoothage"—the gentle, non-irritating action of Metamucil—is indicated in any type of constipation or other gastrointestinal dysfunction requiring a mild, soothing but effective stimulant to bowel evacuation.

metamucil provides a soft, bland, plastic bulk which exerts a stimulating effect on the bowel reflexes and facilitates elimination of the fecal content in a completely normal and natural manner.

metamucil is the highly refined mucilloid of Plantago ovata (50%), a seed of the psyllium group, combined with dextrose (50%), as a dispersing agent.

ican medical schools; the development and administration of industrial dental clinics in various industrial groups; a panel discussion on new preventive measures in industry; a panel discussion on in-service education of the nurse in industry, and many other subjects which can be found by consulting the preliminary program.

Further details and copy of the preliminary program may be secured by writing to Dr. Edward C. Holmblad, Managing Director of the American Association of Industrial Physicians and Surgeons, 28 East Jackson Blvd., Chicago 4, Illinois.

All hotel reservations are made by the Housing Bureau, Buffalo Convention and Tourist Bureau, Inc., 602 Genesee Bldg., Buffalo, N. Y.

DAKOTA COUNTY SOCIETY

All officers of the Dakota County Medical Society were re-elected for 1947 at the annual meeting on January 28 at the Gardner Hotel in Hastings. Dr. Albert J. Emond, Farmington, was retained as president; Dr J. A. Sanford, Farmington, vice president, and Dr. L. R. Peck, Hastings, secretary-treasurer.

The society elected a cancer committee to co-operate with the state and national cancer organizations, naming Dr. A. J. Emond as chairman, and Drs. Leo Burns, South Saint Paul, and L. R. Peck as committee members.

HENNEPIN COUNTY SOCIETY

At a meeting on February 3, it was announced that Dr. Ralph H. Creighton, Minneapolis, had been elected president of the Hennepin County Medical Society. He will take office in October.

Dr. Robert L. Wilder and Dr. William P. Sadler were named vice presidents; Dr. Charles A. Aling, secretary-treasurer, and Dr. Thomas Lowry, librarian. Members elected to various boards are: Drs. Willard D. White and John H. Moe, board of directors; Drs. Edwin G. Benjamin and Otto W. Yoerg, board of censors; Drs. S. Marx White and Vernon L. Hart, board of ethics; and Drs. Henry L. Ulrich and James K. Anderson, board of trustees, Drs. Kenneth Bulkley, O. J. Campbell, Richard H. Crammer and Donald McCarthy were elected delegates to the State Medical Association.

The program for the meeting featured a talk by Dr. Donald W. Hastings, head of the University of Minnesota psychiatry and neurology department, who spoke on "Psychotherapy in General Practice."

McLEOD COUNTY SOCIETY

At the annual meeting of the McLeod County Medical Society, held January 9 at Glencoe, Dr. C. W. Truesdale, Glencoe, was elected president, and Dr. John W. Gridley, Glencoe, secretary. A resolution was passed endorsing the national drive for the infantile paralysis fund.

MINNESOTA SURGICAL SOCIETY

Dr. C. W. Mayo, Rochester, was elected president of the Minnesota Surgical Society at the organization's first postwar meeting, held in Rochester on January 31. The society last met in 1941, when it was decided to discontinue meetings for the duration of the war.

Also elected to office at the January meeting were Dr. O. J. Campbell, Minneapolis, vice president, and Dr. Malcolm G. Gillespie, Duluth, secretary-treasurer.

During the morning session of the one-day meeting, the group was addressed by Drs. M. B. Dockerty and B. T. Horton, Rochester. At the afternoon session, papers were presented by Drs. F. R. Keating, J. H. Grindlay, J. C. Cain, Hiram E. Essex, H. Waltman Walters, S. W. Harrington and F. Z. Havens, all of Rochester.

A dinner was given at the Mayo Foundation House for the society in the evening.

STEARNS-BENTON COUNTY SOCIETY

Dr. Gilman H. Goehrs, St. Cloud, was elected president of the Stearns-Benton County Medical Society at a meeting held in St. Cloud on January 23. Dr. A. H. Zachman, Melrose, was named president-elect for 1948 and also a delegate for 1947.

Others elected to office were Dr. F. H. Baumgartner, Albany, vice president; Dr. John N. Libert, St. Cloud, secretary-treasurer; Dr. R. N. Jones, St. Cloud, alternate delegate, and Dr. S. J. Raetz, St. Cloud, advisory committee chairman.

Dr. Rodney Sturley, Saint Paul, was principal speaker at the meeting, discussing the use of hormones.

The society voted to sponsor the annual essay contest for junior and senior high school students on the subject, "Why Private Practice of Medicine Furnishes This Country with the Finest in Medical Care."

WASECA COUNTY SOCIETY

Re-elected as president, Dr. George H. Olds, New Richland, was chosen to head the Waseca County Medical Society for another term, at the annual meeting held at Hotel Waseca on January 7. Dr. H. M. McIntire, Waseca, was elected vice president, and Dr. S. C. G. Oeljen, Waseca, secretary-treasurer.

The society and the ladies auxiliary, which held its annual meeting at the same time, were entertained at a dinner at the hotel by Dr. and Mrs. Clifford T. Wadd, Janesville.

WASHINGTON COUNTY SOCIETY

The Washington County Medical Society held its regular monthly meeting on February 11. Following a business discussion, a colored motion picture entitled "Intocostrin" was shown through the courtesy of E. R. Squibb and Sons.

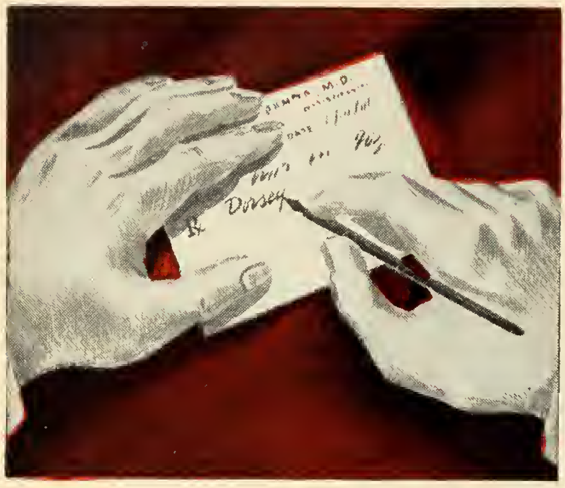
WRITE OR WIRE FOR INFORMATION



You can write it with certainty . . .

Dorsey

Chances are most physicians have never visited the pharmaceutical laboratories where the medications they use routinely are manufactured. You yourself, perhaps could not name the scientific staff or describe the methods followed in your favorite drug house.

One factor you depend upon — "THE NAME OF THE MANUFACTURER." All other factors — laboratory facilities, personnel, procedure — are wrapped up in THE NAME.

Physicians have relied on the name DORSEY (until recently Smith-Dorsey) for over 38 years because the factors behind the name are right. Dorsey laboratories are fully equipped, capably staffed, follow rigidly standardized testing procedures throughout.

When you write the name, do it with certainty . . . "Dorsey."

THE SMITH-DORSEY COMPANY

WOMAN'S AUXILIARY

Blue Earth, Redwood-Brown and Nicollet-Le Sueur Counties

A joint dinner meeting of the medical societies and auxiliaries of Blue Earth, Redwood-Brown and Nicollet-Le Sueur Counties was held on January 20, 1947 with the Nicollet-Le Sueur group as hosts. There was a very large attendance.

Dr. Robert L. Wilder of Minneapolis addressed the group and Dr. Robert N. Barr of the Minnesota State Health Department spoke on the cancer problem and its control.

After the program the various societies and auxiliaries had their individual meetings.

Auxiliary members discussed *Hygeia,* pending legislation and the cancer essay and poster contests.

Hennepin County

The February meeting of the Hennepin County Medical Auxiliary was held February 7, 1947 at the Medical Arts Lounge, Minneapolis.

Dr. Donald W. Hastings of the department of psychiatry at the University of Minnesota talked on "Certain Types of Emotional Illness."

Mrs. John H. Moe was tea chairman for the day, and Mrs. Jalmer H. Simons served as hospitality chairman.

Ramsey County

The January Meeting of Ramsey County Medical Auxiliary was held at the home of Mrs. A. A. Kugler, 1368 Edgcumbe Road, Saint Paul.

Mr. Douglas K. Baldwin of the American Red Cross had as his topic, "Let Us Not Take It for Granted" and Richard Enquist of Saint Paul played a group of violin selections.

Tea followed the program with Mrs. Charles Waas and Mrs. E. C. Bohland pouring.

Awards were presented to two winners of essays on tuberculosis in a contest conducted as part of the Christmas Seal Program—Delores Carley of White Bear High School and Irma Artell of Mechanic Arts High School, Saint Paul.

Upper Mississippi

At a dinner meeting of the Upper Mississippi Medical Auxiliary held January 25, 1947, the following officers were elected: Mrs. A. J. Lenarz, Browerville, president; Mrs. I. L. Mitby, Aitkin, president-elect; Mrs. Virgil Quanstrom, Brainerd, vice president; Mrs. A. M. Mulligan, Brainerd, secretary, and Mrs. A. N. Borgerson, Long Prairie, treasurer.

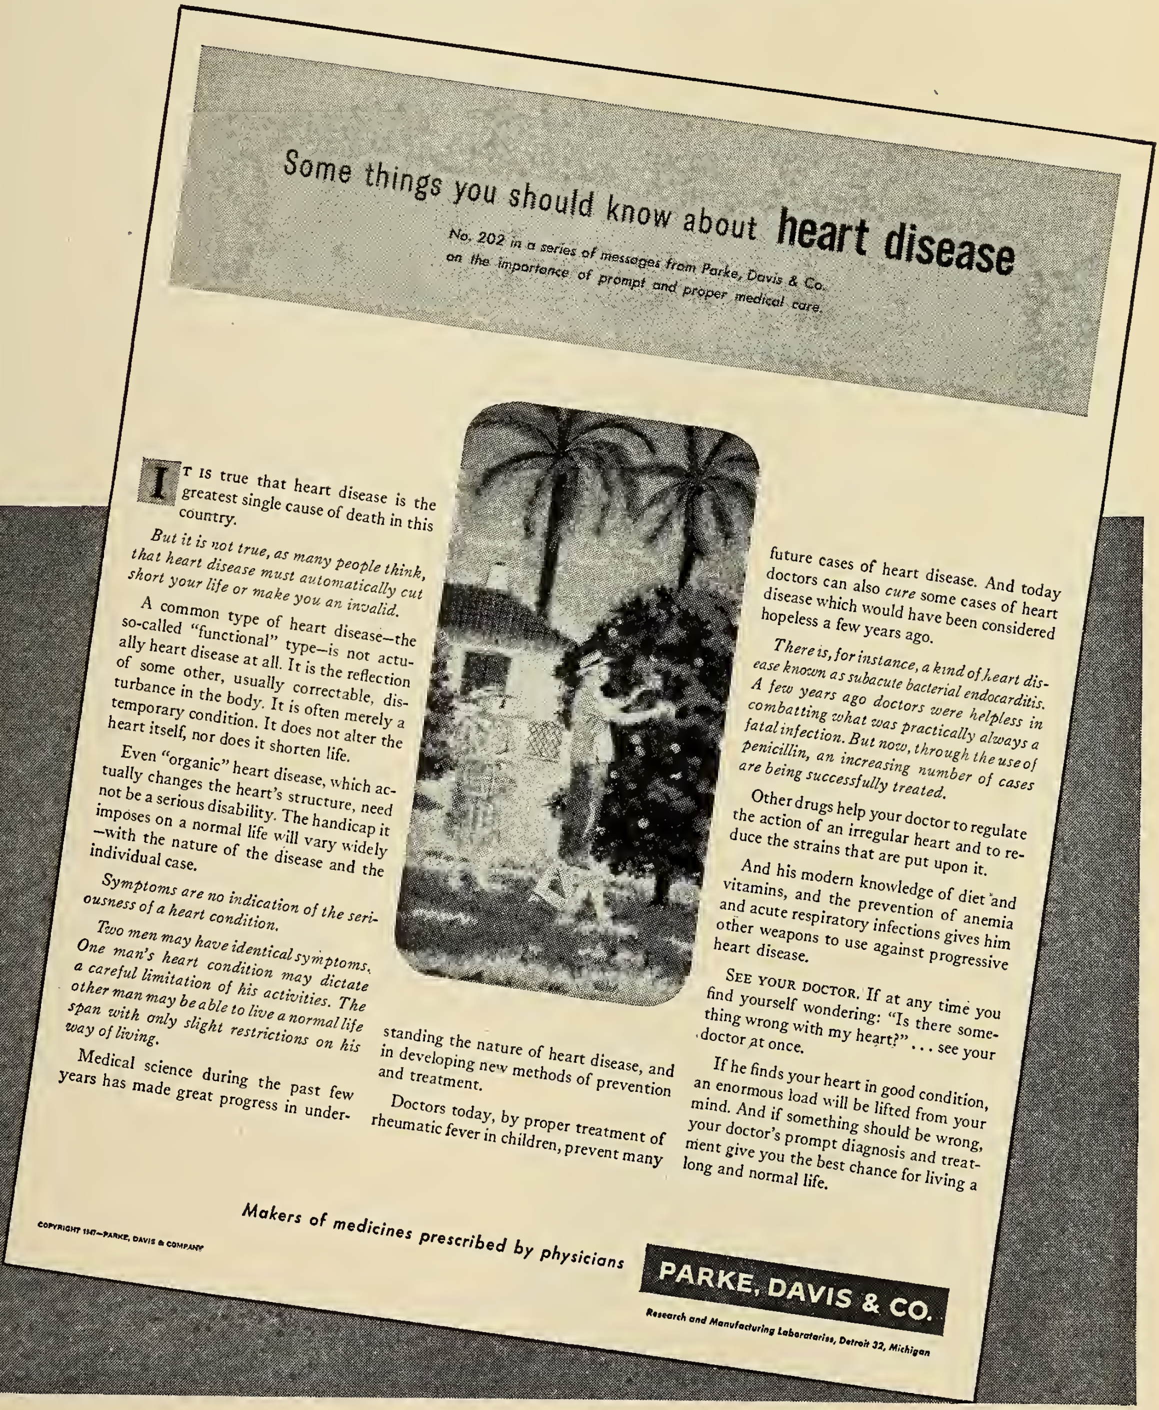
The state cancer society and county nursing projects were discussed at this meeting. Mrs. J. A. Thabes, Sr., State president-elect, reported on the national auxiliary board meeting held recently in Chicago.

The tuberculosis essay contest, sponsored by the auxiliary was very successful. A number of state winners were residents of the Upper Mississippi territory.

The auxiliary voted contributions to the Red Cross, Christmas Seals and the State Cancer Society.

The advice is always "SEE YOUR DOCTOR"

For over 18 years, Parke, Davis & Company has conducted an educational advertising campaign in behalf of the medical profession — teaching the importance of prompt and proper medical care. Now appearing in color in LIFE and other leading magazines, these "See your doctor" messages reach an audience of *more than 23 million people.*



Some things you should know about **heart disease**

No. 202 in a series of messages from Parke, Davis & Co. on the importance of prompt and proper medical care.

It is true that heart disease is the greatest single cause of death in this country.

But it is not true, as many people think, that heart disease must automatically cut short your life or make you an invalid.

A common type of heart disease—the so-called "functional" type—is not actually heart disease at all. It is the reflection of some other, usually correctable, disturbance in the body. It is often merely a temporary condition. It does not alter the heart itself, nor does it shorten life.

Even "organic" heart disease, which actually changes the heart's structure, need not be a serious disability. The handicap it imposes on a normal life will vary widely—with the nature of the disease and the individual case.

Symptoms are no indication of the seriousness of a heart condition.

Two men may have identical symptoms. One man's heart condition may dictate a careful limitation of his activities. The other man may be able to live a normal life span with only slight restrictions on his way of living.

Medical science during the past few years has made great progress in understanding the nature of heart disease, and in developing new methods of prevention and treatment.

Doctors today, by proper treatment of rheumatic fever in children, prevent many future cases of heart disease. And today doctors can also *cure* some cases of heart disease which would have been considered hopeless a few years ago.

There is, for instance, a kind of heart disease known as subacute bacterial endocarditis. A few years ago doctors were helpless in combatting what was practically always a fatal infection. But now, through the use of penicillin, an increasing number of cases are being successfully treated.

Other drugs help your doctor to regulate the action of an irregular heart and to reduce the strains that are put upon it.

And his modern knowledge of diet and vitamins, and the prevention of anemia and acute respiratory infections gives him other weapons to use against progressive heart disease.

See your doctor. If at any time you find yourself wondering: "Is there something wrong with my heart?" . . . see your doctor at once.

If he finds your heart in good condition, an enormous load will be lifted from your mind. And if something should be wrong, your doctor's prompt diagnosis and treatment give you the best chance for living a long and normal life.

In Memoriam

CLARENCE MARTIN JACKSON

Dr. Clarence Martin Jackson, professor emeritus of anatomy and former head of the department at the University of Minnesota, died January 17, 1947, of Parkinson's disease after a long disabling illness. He retired from the University in 1941 before the completion of his term of service because of his disability.

Dr. Jackson was born in WhatCheer, Iowa, April 12, 1875 and was seventy-one years old at the time of his death. He received the B.S., M.S., and M.D. degrees from the University of Missouri, and in 1923 he was awarded the LL.D. degree by the University of Missouri in recognition of his services to education.

Shortly after receiving his M.D. degree, Dr. Jackson was made professor of anatomy and head of the department at the University of Missouri, and later he was appointed dean of the medical school. In 1913 he accepted the appointment as head of the Department of Anatomy at the University of Minnesota, which position he held until his retirement in 1941.

Dr. Jackson was long recognized as a leader in medical research. He was acting dean of the graduate school at Minnesota for several years while Dean Ford was on leave of absence; and in 1923-24 he was chairman of the Medical Division of the National Research Council. He was a fearless champion of research during the trying period when the Minnesota Medical School was being transformed from an ordinary medical college to the brilliant teaching and research position which it has now attained. Only those of the faculty who were here during that period realize the courage and tact which he constantly displayed in bringing about each small advance to a higher level of scholarship.

During a large part of his active life Dr. Jackson was interested in the effects of nutrition upon growth, and his earlier extensive investigations were summarized in 1925 in his book entitled "The Effects of Inanition and Malnutrition upon Growth and Structure."

During the next five years he extended these interests to a study of body build and physique in university students, and much of this work was incorporated in a book in 1930, jointly published by J. A. Harris, C. M. Jackson, D. G. Patterson and R. E. Scammon, entitled "The Measurement of Man."

In the next decade he returned to his earlier interests, analyzing especially the effect of protein and fat-deficient diets on growth. Also, these years were increasingly occupied by his contribution to the teaching of anatomy. In 1933, the ninth edition of Morris Human Anatomy was published under his editorship and he was working on the tenth edition when obliged to turn it over to another because of ill health. Finally, just as he retired, his monumental Report (to the American Association of Anatomists) of the Committee on Anatomical Nomenclature, of which he was chairman, was published. In 1922-24 he had been president of the Association.

The local chapter of Phi Beta Pi medical fraternity, of which Dr. Jackson was a member, has for several years sponsored an annual lecture called the "Jackson Lecture," in which many distinguished scientists have participated.

In the death of Dr. Jackson the Medical School has lost one of its most distinguished professors, and one who will long be remembered lovingly by the hundreds of students who came under the influence of his teaching.

E. T. Bell

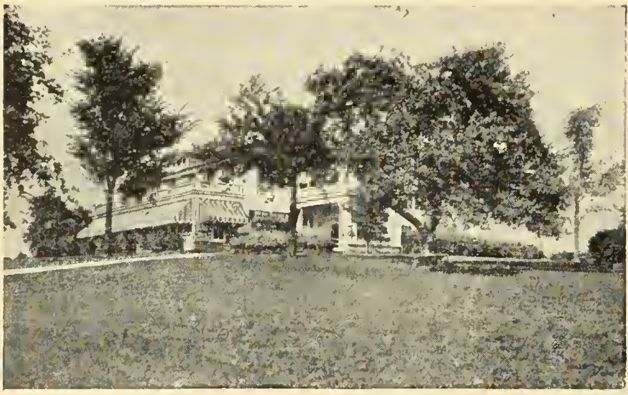
CHEST X-RAY SURVEY

A program unique in the history of health service is being planned for this spring and summer in Minneapolis. Every resident over fifteen will be given the opportunity for a free chest x-ray.

Three mobile x-ray units and seven portable units will be in operation at the same time in various locations in the city beginning May 5. No one will walk more than four blocks for a chest x-ray. Employes in industries which have not already taken advantage of this service will be able to have an x-ray at the plant.

The purpose of this health program is to locate unsuspected cases of tuberculosis, cancer of the lung and heart diseases, according to Dr. Frank J. Hill, city Commissioner of Health.

The program is being sponsored by the Hennepin County Medical Society and the Hennepin County Tuberculosis Association. It is being directed by the Minneapolis Health Department with the co-operation of the U. S. Public Health Service.



The Mary E. Pogue School

Complete facilities for training Retarded and Epileptic children educationally and socially. Pupils per teacher strictly limited. Excellent educational, physical and occupational therapy programs.

Recreational facilities include riding, group games, selected movies under competent supervision of skilled personnel.

Catalogue on request.

Why do Sally, Irene and Mary need vitamin D ?

Growing children require vitamin D mainly to prevent rickets. They also need vitamin D, though to a lesser degree, to insure optimal development of muscles and other soft tissues containing considerable amounts of phosphorus . . . Milk is the logical menstruum for administering vitamin D to growing children, as well as to infants, pregnant women and lactating mothers. This suggests the use of Drisdol in Propylene Glycol, which diffuses uniformly in milk, fruit juices and other fluids.

Average daily dose for infants 2 drops, for children and adults 4 to 6 drops, in milk. Available in bottles of 5, 10 and 50 cc. with special dropper delivering 250 U.S.P. units per drop.

Of General Interest

Dr. H. P. Van Cleve, formerly of Minneapolis, is now located at Dodge Center.

* * *

Drs. A. E. Henslin and Merrill Henslin have moved into a newly furnished suite of offices in Le Roy.

* * *

Dr. C. F. Medlin, Truman, recently moved into his newly constructed office building and is conducting his practice there.

* * *

Dr. F. J. Kucera, Hopkins, attended the twentieth annual convention of the National Conference on Medical Service held in Chicago in February.

* * *

Dr. Paul R. Lipscomb, Rochester, attended the Watson-Jones Fracture Clinic held recently in Chicago under the auspices of the University of Kansas.

* * *

Dr. Frederick Gunlaugson, Moorhead, formerly with the Fargo Clinic, has joined the staff of the state hospital in Fergus Falls. Mrs. Gunlaugson, the former Dr. Eleanor Iverson, was once a member of the same staff.

Dr. Albert V. Stoesser is now located in a new office at 1409 Willow Street, Loring Park, Minneapolis, where he is continuing his practice in allergy and pediatrics.

* * *

Dr. Thomas L. Pool, Rochester, discussed "Some of the Common Errors in Urology" at a meeting of the Ramsey County Medical Society in Saint Paul.

* * *

Dr. E. V. Allen, Rochester, spoke on the clinical use of anticoagulants at a meeting of the Cincinnati Academy of Medicine.

* * *

Dr. Harold N. Rygh, who practiced for a short time in Cokato following his discharge from military service, recently moved to Atwater and opened offices there.

* * *

Opening of a new office in downtown Jackson has been announced by Drs. W. H. Halloran and W. B. Wells of that city.

* * *

Dr. Joseph F. Schaefer, Owatonna, was unanimously elected president of the Steele County Mass X-Ray Committee at the organization meeting held in Owatonna.

Dr. Henry Van Meier, Stillwater, was reappointed county physician at a meeting of the Washington County commissioners in January.

* * *

Dr. O. V. Johnson, Fergus Falls, has accepted a position as medical consultant in the legal department of the Veterans Administration in Minneapolis.

* * *

Dr. W. W. Brown, who has been with the Veterans Bureau in Minneapolis for the past fourteen years, has moved to Isle where he has opened his practice.

* * *

Dr. L. G. Smith, Montevideo, was one of the twenty-one Minnesota physicians who recently incorporated the Minnesota Medical Service, a nonprofit organization for voluntary prepaid medical care.

* * *

Dr. Chester A. Anderson, formerly of Buffalo, who was recently discharged from the armed forces, has moved to Winsted where he has opened an office for the practice of medicine.

* * *

Dr. T. H. Leitschuh, formerly of Sleepy Eye, has become an associate of Dr. J. A. Cosgriff in Olivia. Since his discharge from the navy after three years of service, Dr. Leitschuh has lived in Minneapolis.

* * *

Two lectures were delivered by O. T. Clagett, Rochester, at a postgraduate course at the George Washington University School of Medicine in Washington, D. C. Dr. Clagett spoke on "Surgery of the Pancreas" and "Recent Advances in Surgery of the Biliary Tract."

* * *

On February 8 in Chicago Dr. John D. Camp, Rochester, presided at the fourteenth annual conference of the Teachers of Clinical Radiology, sponsored by the Commission on Education of the American College of Radiology, of which Dr. Camp is chairman.

* * *

Dr. John M. Waugh, Rochester, presented two papers at a meeting of the Sioux Valley Medical Association, in Sioux City, Iowa. His subjects were "The Acute Conditions of the Abdomen" and "Management of Pelvic Tumors."

* * *

Drs. W. M. Balfour and W. L. Benedict, Rochester, have been named members of the Board of Governors of the American College of Surgeons. Dr. G. B. New, also of Rochester, has been named second vice president of the organization.

* * *

Both Dr. Richard Magraw and Dr. R. F. Mueller, Two Harbors, have discontinued their practice in Lake County. Dr. Magraw has moved to Saint Paul. Dr. Mueller has been enjoying a two-month vacation and has not yet announced his future plans.

two traumas

The sick or injured patient is almost simultaneously subjected to two traumas—the basic pathologic process and tissue malnutrition—for malnutrition almost always begins "as soon as injury or disease occurs."[1] Recognition of the vitamin depleting role of dietary restrictions, increased metabolism, glucose infusions, and impairment of absorption, has brought with it the realization that vitamins must be administered in therapeutic—not maintenance—dosages when multiple deficiencies complicate disease. Upjohn provides a full range of maintenance and therapeutic vitamin preparations for oral and parenteral administration.

Prevent INFECTION with MERCUROCHROME

(H. W. & D. brand of merbromin, dibromoxymercurifluorescein-sodium)

Extensive use of the Surgical Solution of Mercurochrome has demonstrated its value in preoperative skin disinfection. Among the many advantages of this solution are:

Solvents which permit the antiseptic to reach bacteria protected by fatty secretions or epithelial debris.

Clear definition of treated areas. Rapid drying.

Ease and economy of preparing stock solutions.

Solutions keep indefinitely.

The Surgical Solution may be prepared in the hospital or purchased ready to use.

Mercurochrome is also supplied in Aqueous Solution, Powder and Tablets.

Formation of the Montevideo Clinic took place in January through the association of Dr. L. R. Lima, Jr., and Dr. W. A. Owens, Montevideo. Their now-combined offices have been remodeled and a considerable amount of new equipment has been installed.

* * *

Dr. F. M. McCarten, Stillwater, was appointed coroner by the Washington County commissioners on February 4. A deputy coroner for several years, Dr. McCarten succeeded Dr. J. H. Haines, who had resigned from the office.

* * *

Principal speaker at a meeting of the Arrowhead Society of Medical Technologists, Duluth, was Dr. W. V. Knoll, pathologist at St. Mary's Hospital. Dr. Knoll discussed a color film, "Animated Hematology," which dealt primarily with the blood and bone findings in macrocytic anemias.

* * *

Dr. J. S. Blumenthal, Minneapolis, has been elected chief of staff of St. Andrew's Hospital. Dr. Blumenthal, a practicing physician and surgeon in the Columbia Heights district of Minneapolis for over twenty years, is also an assistant clinical professor of medicine at the University of Minnesota.

* * *

Dr. J. L. Mills, Winnebago, was a member of a delegation which visited Saint Paul in January to get information from the State Board of Health in regard to state recommendations as to hospital building. A hospital drive is planned by Winnebago citizens for this spring.

* * *

Dr. W. R. Lovelace II, Rochester, has announced his resignation from the staffs of the Mayo Clinic and Mayo Foundation to continue the practice of his uncle in Albuquerque, New Mexico. While at the Mayo Clinic, Dr. Lovelace did experimental work with the BLB mask in high altitude flying.

* * *

Dr. C. Anderson Aldrich, Rochester, pediatrician at the Mayo Clinic, spoke on the Rochester child health project at a meeting of the Minneapolis Community Health Service, February 10. Dr. Aldrich also recently addressed the American Orthopsychiatric Association in Cincinnati on "The Pediatrician Looks at Personality."

* * *

Announcement has been made by the Doms-Pierson Clinic, Slayton, of the recent entry of Dr. Richard M. Johnson into the partnership.

Dr. Johnson, a graduate of the University of Nebraska School of Medicine in 1942, was formerly at Manning, Iowa, after completing a tour of service in the navy.

* * *

Dr. Myron O. Henry, Minneapolis, was named president-elect of the American Academy of Orthopedic Surgeons at a recent meeting in Chicago. Dr. Henry,

who is president of the Clinical Orthopedic Society and present secretary-treasurer of the Academy, will assume his new office in January, 1948, succeeding Dr. Rex L. Diveley, New York.

* * *

Dr. Walter C. Alvarez, professor of medicine at the Mayo Foundation, Rochester, spoke at the thirty-seventh annual meeting of the Jewish Family and Children's Service of Minneapolis, held February 19 at the Radisson Hotel in Minneapolis. An internationally recognized authority on psychosomatic medicine, Dr. Alvarez discussed "What Makes People Sick."

* * *

Dr. W. E. Macklin, Jr., Litchfield, joined the staff of the Mankato Clinic on March 1 as radiologist. A physician in Litchfield for twelve years, Dr. Macklin served in the navy in World War II. Since his discharge, he has been taking graduate work in the Department of Radiology at the University of Minnesota. He recently passed the examination of the American Board of Radiology.

* * *

Dr. Waltman Waters, Rochester, and Dr. Shields Warren, assistant professor of pathology, Harvard Medical School, have been appointed to serve on the National Advisory Cancer Council by Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service. Dr. Walters was first appointed to the Council in 1941, but service in the navy interrupted his connection with the Council.

* * *

On January 20, 1947, Drs. Robert E. Priest, Lawrence R. Boies and Neill F. Goltz presented a paper at the Middle Section meeting of the American Laryngological, Rhinological and Otological Society in Chicago. The paper summarized the experiences at the University of Minnesota Hospitals and the Minneapolis General Hospital with tracheotomy in bulbar poliomyelitis during the epidemic of 1946.

* * *

Dr. Alfred S. Nelson, Thief River Falls, has become affiliated with the Bratrud Clinic of that city, specializing in internal medicine. A graduate of the University of Minnesota Medical School in 1943, Dr. Nelson interned at Ancker Hospital, Saint Paul, and then served for twenty-six months in the army medical corps. His major assignment was at a general hospital in Manila, Philippine Islands.

* * *

Dr. Robert M. Watson, formerly of Royalton, is now affiliated with the Bratrud Clinic in Thief River Falls, in the capacity of obstetrician and gynecologist. Following graduation from the University of Minnesota Medical School and internship at Miller Hospital, Saint Paul, Dr. Watson served for eighteen months in the army medical corps. While stationed at Lovell General Hospital, Fort Devens, Massachusetts, he was assistant chief of surgery in charge of obstetrics and gynecology.

Under the subsidization of the Hennepin County Tuberculosis Association, a broad new health program is being launched in Minneapolis public schools, with Helen Starr, associate professor of physical education at the University of Minnesota, as director.

In addition to handling accident and emergency cases, the health program includes careful control of communicable diseases, emphasis on physical education for every child in school, and intensified health instruction.

* * *

"Cicatricial Stenosis of the Nasopharynx: Correction by Means of a Skin Graft" was the subject of a talk by Dr. F. A. Figi, Rochester, before the Southern Section of the American Laryngological, Rhinological and Otological Society, at a meeting in Miami Beach, Florida. While in Florida, Dr. Figi also presented two papers at the midwinter postgraduate course in otolaryngology and ophthalmology held by the Graduate School of Medicine of the University of Florida.

* * *

Offices have been opened at the Two Harbors Hospital by Dr. Ralph Papermaster and Dr. Harry N. Simmonds. Dr. Papermaster, who is specializing in surgery, was a surgical resident at Minneapolis General Hospital for three years, and served as head of an army surgical team in the European theatre for two years. Dr. Simmonds, who will do general practice, interned at Columbus Hospital in New York City and then served for two and one-half years in the army medical corps.

Dr. Ward Norton Van Potter and Dr. Viola Ellen Sheridan, both of whom hold Fellowships at the Mayo Clinic, were married on December 28, 1946, in Rochester. Dr. Sheridan, a graduate of the Medical College of Creighton University, Omaha, Nebraska, interned at the Women's and Children's Hospital in San Francisco. Dr. Potter, a graduate of the Medical College of the University of Toronto, Ontario, interned at the General Hospital in Montreal, Quebec, Canada.

* * *

Dr. Francis E. Harrington, former superintendent of Minneapolis General Hospital and former commissioner of Minneapolis, was praised in an article in a recent issue of the *Journal-Lancet* for building an outstanding anti-tuberculosis program for Minneapolis. The article, written by Dr. J. A. Myers, professor of public health at the University of Minnesota, states: "Under Dr. Harington's leadership, tuberculosis has reached such a low ebb in Minneapolis that workers are beginning to talk about eradication, rather than control of the disease."

* * *

CORRECTION—In the announcement of the opening of the offices of Dr. Frank W. Quattlebaum and Dr. Jane E. Hodgson, which appeared in the January issue of MINNESOTA MEDICINE, it was incorrectly stated that Dr. Quattlebaum had served a fellowship in obstetrics and gynecology at the Mayo Clinic. Dr. Quattlebaum took his training in surgery at the University of Minne-

sota and at the Mayo Clinic. His associate, Dr. Jane Hodgson, completed her fellowship in obstetrics and gynecology at the Mayo Clinic in 1944 and is limiting her practice to this specialty.

* * *

Believed to be Minnesota's oldest practicing physician, Dr. George D. Haggard, Minneapolis, celebrated his ninetieth birthday on January 18.

Born in 1857 in Fairpoint, near Rochester, while Minnesota was still a territory, Dr. Haggard has served three generations of many of the state's oldest families. He graduated from the University of Minnesota Medical School in 1893 and interned at Minneapolis General Hospital. For four years he was health officer of Minneapolis. At present he is on the staff of Northwestern and Asbury hospitals. He still answers many calls, though a heart attack six months ago forced him to curtail his activities.

* * *

Dr. and Mrs. Moses Barron, Minneapolis, were guests of honor at the annual Jewish National Fund dinner, held January 26 at the Radisson Hotel. In recognition of Dr. and Mrs. Barron's twenty-five years of leadership in Minneapolis Jewish affairs, nearly 100 organizations gathered to present the couple with a book bearing the names of contributors to the development of a forest in Palestine that will be named for the Barrons.

Dr. Barron, a professor of medicine at the University of Minnesota, is a past president of the Hennepin County Medical Society, the Minnesota Society of Internal Medicine, the Minnesota Pathological Society, and the Minneapolis Academy of Medicine.

* * *

Dr. Victor Johnson, Chicago, dean of students in biology and medicine and professor of physiology at the University of Chicago, will become director of the Mayo Foundation for Medical Education and Research next fall. He will succeed Dr. Donald C. Balfour, present director, who is scheduled to retire in October, 1947.

Dr. Johnson, author of several articles and books, is a member of numerous scientific and educational organizations and is on the advisory committee of the Surgeon General, United States Public Health Service, in administration of the Federal Hospital Survey and Construction Act. To accept the Mayo appointment, he resigned as secretary of the AMA Council on Medical Education and Hospitals.

Following retirement, Dr. Balfour, who has been director of the Mayo Foundation since 1937, will serve as director emeritus and as professor of surgery emeritus in the University of Minnesota graduate school.

Hibbing General Hospital has selected Dr. T. A. Estrem as chief of staff, Dr. C. N. Harris as vice president, and Dr. T. R. Schweiger as secretary.

Department heads named at a staff meeting in January are Dr. L. W. Johnsrud, surgery; Dr. L. S. Nelson, internal medicine; Dr. L. W. Morsman, ophthalmology; Dr. Andrew Sinimark, otolaryngology; Dr. C. N. Harris, pediatrics; Dr. Frank Bachnik, obstetrics; Dr. A. C. Tingdale, communicable diseases and contagion; Dr. C. S. Raadquist, x-ray; and Dr. Randall Derifield, laboratory.

* * *

The position of executive administrator of Northwestern Hospital, Minneapolis, was assumed on March 1 by Russell Nye, former administrator of the Dallas, Texas, city-county hospital system.

Mr. Nye, who before his new appointment was president-elect of the Texas Hospital Association has held administrative positions at Michael Reese Hospital in Chicago, Crawford-Long Memorial Hospital in Atlanta, and the University of Iowa Hospitals. He succeeds Colonel Harry Brown, who has been on military leave and who will return to active army duty.

* * *

Chief of staff of St. Luke's Hospital, Duluth, for 1947 is Dr. A. O. Swenson, who was recently elected to succeed Dr. Anderson C. Hilding.

Also named by the hospital staff were Dr. Gordon C. MacRae, vice chief of staff; Dr. J. R. Manley, chief of obstetrics; Dr. Peter S. Rudie, chief of surgery; Dr. R. E. Nutting, chief of pediatrics; Dr. M. F. Fellows, chief of eye, ear, nose and throat; and Dr. A. H. Wells, chief of pathological laboratories. Dr. F. J. Hirschboeck, Dr. A. L. Abraham, and Dr. C. M. Bagley, secretary, were named to the executive committee.

* * *

Earl C. Wolf, purchasing agent of St. Mary's Hospital in Rochester, was named president of the Minnesota

REST HOSPITAL

A quiet, ethical hospital with therapeutic facilities for the diagnosis, care and treatment of Nervous and Medical cases. Invites coöperation of all reputable physicians who may supervise the treatment of their patients.

EXCELLENT CARE TO CONVALESCENT AND CHRONIC PATIENTS

Rates Reasonable. Patients under the care of their own physicians, who direct the treatment.

5511 Lyndale Ave. So. LO. 0773 Minneapolis, Minn.

Hospital Association at a meeting of the board of directors in Minneapolis on January 18.

Former first vice president of the Association, Mr. Wolf was appointed to serve out the unexpired term of the late W. W. Sherman, who was superintendent of the Naeve Hospital in Albert Lea. His tenure will expire May 15, when the Association holds its annual meeting in Minneapolis.

Emil Hanson, superintendent of Winona General Hospital, was elected to Mr. Wolf's former office.

* * *

Election of Dr. L. R. Gowan as chief of staff of St. Mary's Hospital, Duluth, was announced on February 7. He replaces Dr. J. E. Power in the position.

Other staff officers of the hospital, elected at the same time, are Dr. C. O. Kohlbry, president-elect; Dr. F. T. Becker, secretary of the staff; Dr. R. P. Buckley, chief of pediatrics, and Dr. A. J. Bianco, chief of surgery.

Officers continuing from 1946 are Dr. Frank Cole, chief of anesthesiology; Dr. J. A. Winter, chief of eye, ear, nose and throat; Dr. C. W. Taylor, chief of contagion; Dr. E. L. Tuohy, chief of laboratories; Dr. Richard Bardon, chief of medicine; Dr. L. E. Schneider, chief of neurology; Dr. J. R. Moe, chief of obstetrics; Dr. M. H. Tibbetts, chief of orthopedics, and Dr. M. A. Nicholson, chief of urology.

MASSIVE GASTRIC HEMORRHAGE

(Continued from Page 319)

Discussion

Dr. Hamlin Mattson: In the first section you showed, isn't that sufficient to give a diagnosis of ulcer in the mucous membrane?

Dr. G. H. Hall: Yes. The pathologist called it a small acute ulcer.

Dr. Hamlin Mattson: From what part of the stomach was that taken?

Dr. G. H. Hall: The posterior upper portion of the resection.

Dr. John R. Paine: I should like to ask some of the experienced surgeons what a surgeon is supposed to do if he operates for an ulcer and does not find an ulcer. Do you leave the stomach in or take it out?

Dr. Willard White: I don't pretend to be able to answer the question, but if you have a patient into whom you are pouring blood and he is pouring it back as fast as you pour it in, you have to do something, and I think that resection is exactly the thing to do. I have had to make this same decision, myself.

Dr. John R. Paine: It is a pure and simple gamble. The only bad thing is that you have to take out the stomach. The ulcer may be somewhere else.

Dr. J. M. Hayes: In speaking of gastric hemorrhage, we must refer back to a previous discussion before this society on the use of Koagmin. Dr. Arnold Jackson of Madison popularized this drug in this vicinity. Those who have given it a trial are usually enthusiastic about the results. I have used it several times in case of severe gastric hemorrhage and agree with Jackson that it will often check the hemorrhage sufficiently to defer an emergency operation.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

Practical Physiological Chemistry. Twelfth Edition. Philip B. Hawk, Ph.D., President and Bernard L. Oser, Ph.D., Director, Food Research Laboratories, Inc., New York; and William H. Summerson, Ph.D., Associate Professor of Biochemistry, Cornell University Medical College, New York. 1323 pages. Illus. Price, $10.00, cloth. Philadelphia: The Blakiston Co., 1947.

Radiology for Medical Students. Fred Jenner Hodges, M.D., Professor and Chairman, Department of Roentgenology, University of Michigan; Isadore Lampe, M.D., Associate Professor, Department of Roentgenology, University of Michigan, and John Floyd Holt, M.D., Assistant Professor, Department of Roentgenology, University of Michigan. 424 pages. Illus. Price, $6.75, cloth. Chicago: Year Book Publishers, 1947.

The Compleat Pediatrician. Practical, Diagnostic, Therapeutic and Preventive Pediatrics. Fifth Edition. Wilbur C. Davison, M.A., D.Sc., M.D., Professor of Pediatrics, Duke University School of Medicine and Pediatrician Duke Hospital; formerly Acting Head of Department of Pediatrics, Johns Hopkins University School of Medicine, etc. Price, $3.75 check with order, or $4.00 on credit, cloth. Durham, N. C.: Duke University Press, 1946.

Fundamentals of Clinical Neurology. H. Houston Merritt, M.D., Professor of Clinical Neurology, College of Physicians and Surgeons, Columbia University; Chief of Division of Neuropsychiatry, The Montefiore Hospital; Fred A. Mettler, M.D., Ph.D., Associate Professor of Anatomy, College of Physicians and Surgeons, Columbia University, and Tracy Jackson Putnam, M.D., Professor of Neurology and Neurological Surgery, College of Physicians and Surgeons, Columbia University, New York. 289 pages. Illus. Price, cloth, $6.00. Philadelphia: The Blakiston Co., 1947.

Health Examinations. A Manual for the General Practitioner. Prepared for Medical Society of the County of New York, by the Special Committee on Preventive Medicine. 144 pages, paper cover. Presented with the compliments of Mead Johnson & Company, Evansville, Indiana, 1947.

SHOCK TREATMENTS AND OTHER SOMATIC PROCEDURES IN PSYCHIATRY. L. B. Kalinowsky, M.D., Research Associate in Psychiatry, College of Physicians and Surgeons Columbia University, and New York State Psychiatric Institute and Hospital, Assistant Neurologist, Neurological Institute of New York; and Paul H. Hoch, M.D., Assistant Clinical Psychiatrist, New York State Psychiatric Institute and Hospital; Instructor in Psychiatry, College of Physicians and Surgeons, Columbia University. 320 pages. Price $4.50. New York: Grune & Stratton, Inc., 1946.

This is a very well-organized, authoritative, easy-to-read treatise on, primarily, shock treatment but it deals also with other somatic non-surgical treatment, prefrontal lobotomy, and theoretical considerations in relation to this phase of psychiatric therapy.

A brief review of historical development is given, and comprehensive and detailed practical instruction in the

use of insulin shock treatment and the convulsive therapy is carefully outlined.

The authors have been identified for several years in practical work in research on new procedures in the treatment of mental illness and are highly qualified to present their findings and opinion in an authoritative fashion.

This book is highly recommended to the psychiatrist and neurologist. Every important problem is carefully considered. Specific references and an excellent bibliography of several hundred important papers and books will aid the specialist to find further details on any point that is of particular interest to him.

The rooster's legs are straight.

The boy's are not.

The rooster got plenty of vitamin D.

Fortunately, extreme cases of rickets such as the one above illustrated are comparatively rare nowadays, due to the widespread prophylactic use of vitamin D recommended by the medical profession.

One of the surest and easiest means of routinely administering vitamin D (and vitamin A) to children is MEAD'S OLEUM PERCOMORPHUM WITH OTHER FISH-LIVER OILS AND VIOSTEROL. Supplied in 10-c.c. and 50-c.c. bottles. Also supplied in bottles of 50 and 250 capsules. Council Accepted. All Mead Products Are Council Accepted. Mead Johnson & Company, Evansville 21, Ind., U.S.A.

For estrogenic therapy THEELIN is offered in ampoule form. Protection of potency and sterility of the original pure crystalline hormone are afforded by this individualized packaging.

THEELIN for Therapy

Climacteric symptoms in varying degrees of intensity may be expected in 80 per cent of women as they enter and pass through phases of the menopause. THEELIN often negates or decreases typical manifestations associated with this condition.

rating: continuous

. . . even on self-rectified current

Forced oil circulation within the sealed-off tube housing, coupled with large volume air-blast, so increases its heat dissipation rate that the "Airflow" tube can be operated *continuously, even on self-rectified current*...the only tube so rated. This unique design principle* is another example of the trail-blazing engineering which has made the Picker hallmark on x-ray equipment a symbol of consistently high performance over an exceptionally long life.

Picker **sets the pace in X-ray**

Eminent critic . . . . . dietary dub!

At meal time his renowned judgment deserts him. Eating only the food he likes, a choice of notably limited range, he thrice daily produces a burlesque on proper nutrition. Inevitably, this perennial first-nighter makes his entrance into some physician's reception room—the victim of a self-made, borderline vitamin deficiency. In the same cast, you will find other familiar types. Included in it are the ignorant and indifferent, people "too busy" to eat properly, those on self-imposed and badly balanced reducing diets, excessive smokers, food faddists and alcoholics, to name a few. First thought in such cases is dietary reform, of course. Along with that, a dependable vitamin supplement may well be in order. When you prescribe an *Abbott* vitamin product, you are assured that the patient will receive the full vitamin potencies intended. Your pharmacy carries a complete line of Abbott vitamin products in a variety of dosage forms and package sizes, and will be pleased to fill your prescriptions. ABBOTT LABORATORIES, NORTH CHICAGO, ILLINOIS.

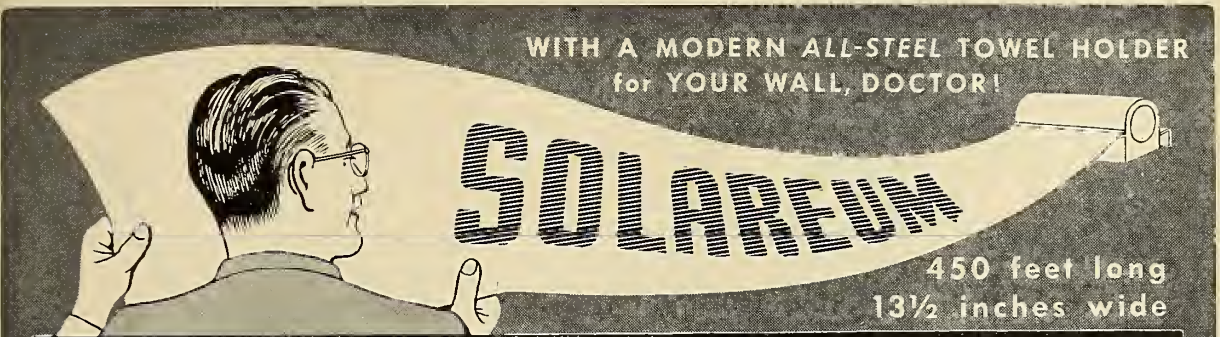
Abbott Vitamin Products



ABSORBENT—LINTLESS

PAPER TOWEL

THIS excellent Paper Towel is not only sanitary and absorbent, but it is entirely free of lint. Because like other SOLAREUM products, it was produced expressly for you, doctor.

For wiping the hands after washing; for a cover on the headrest of your examining table; as a paper napkin for the food tray; or, as a temporary floor mat for the barefoot patient, and numerous other expedients, this Paper Towel serves the purpose well. There is nothing else like it.

In each roll you get 450 running feet of towel, 13½ inches wide, tightly wound so that the roll is only 4½ inches in diameter. Plenty of towel to last you a long time.

Price per roll, $3.40

ALL-STEEL, ENAMELED

TOWEL HOLDER

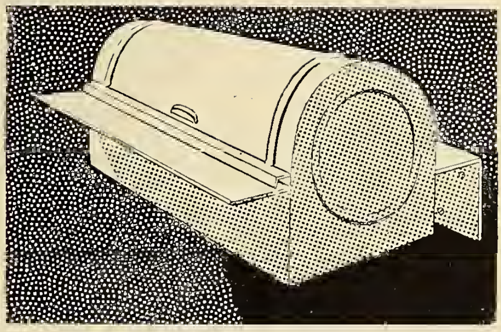
A Practical, Sanitary Towel Dispenser

Built of heavy sheet steel and carefully welded, to last a lifetime. Holds one roll of SOLAREUM Towel. Finish in durable baked enamel. Easily fastened on wall or partition with screws furnished. Dustproof, and secure. Nothing to get out of order.

Towel pulls out over steel ledge which serves as cutting edge, to give you any length of towel you need for the moment.

Choice of white enamel or walnut color. Special Finish at extra cost.

Price, walnut or white,
$7.85



Ask our salesman about this generous size Paper Towel, with Holder for your wall, or write direct to us.

We also supply SOLAREUM Paper Table Sheeting, continuous rolls and individual sheets, to cover every need for examining tables.

Pyribenzamine hydrochloride—Ciba's anti-histaminic—has won prompt recognition since its recent introduction. It has proved successful in a high percentage of cases of urticaria, hay fever, asthma; and today is widely prescribed.

COUNCIL ACCEPTANCE

Pyribenzamine now has been formally accepted by the A.M.A. Council on Pharmacy and Chemistry. A report to the Council on anti-histaminic agents was written by S. M. Feinberg, M.D., in the November 23, 1946 issue of the J.A.M.A. Pyribenzamine was found to be highly effective, and produces relatively few side effects.

doctor is spared
lawyer's grief

The doctor hit it right on the button!

▶ In choosing the *complete* kind of malpractice insurance and service (the Medical Protective kind), he bought protection against *any* malpractice charge, however serious, that might be made by rich man, poor man, beggarman or thief.

▶ He has spared himself loss of time, money and reputation—and all the grief which will now be borne solely by the world's largest legal staff of malpractice experts.

▶ Not only will their confidential service assure him of prompt and unhurried attention to his best interests in prevention of suits, but they will cooperate with legal counsel (whom the doctor helps choose) in fighting any and all suits through the court of last resort.

▶ All cost of defense is paid by us. We also pay the judgment, if awarded, as provided in our policy. Yet our annual premium is about the cost of a good hat.

Solomon Grundy

There are still too many Solomon Grundys—"born on Monday...died on Saturday"—for despite the gratifying decline in infant mortality, *there is still only slight reduction in the number of deaths of infants under one month.* To better an infant's chance of survival, the first feedings—and the right formula—can do much to minimize the early hazards to life.

'Dexin' has proved an excellent "first carbohydrate" because of its high dextrin content. It (1) resists fermentation by the usual intestinal organisms; (2) tends to hold gas formation, distention and diarrhea to a minimum, and (3) promotes the formation of soft, flocculent, easily digested curds.

Simply prepared in hot or cold milk, 'Dexin' brand High Dextrin Carbohydrate is well taken and well retained. 'Dexin' *does* make a difference.

HIGH DEXTRIN CARBOHYDRATE 'Dexin'
BRAND

Composition—Dextrins 75% • Maltose 24% • Mineral Ash 0.25% • Moisture 0.75% • Available carbohydrate 99% • 115 calories per ounce • 6 level packed tablespoonfuls equal 1 ounce • Containers of twelve ounces and three pounds • Accepted by the Council on Foods and Nutrition, American Medical Association.

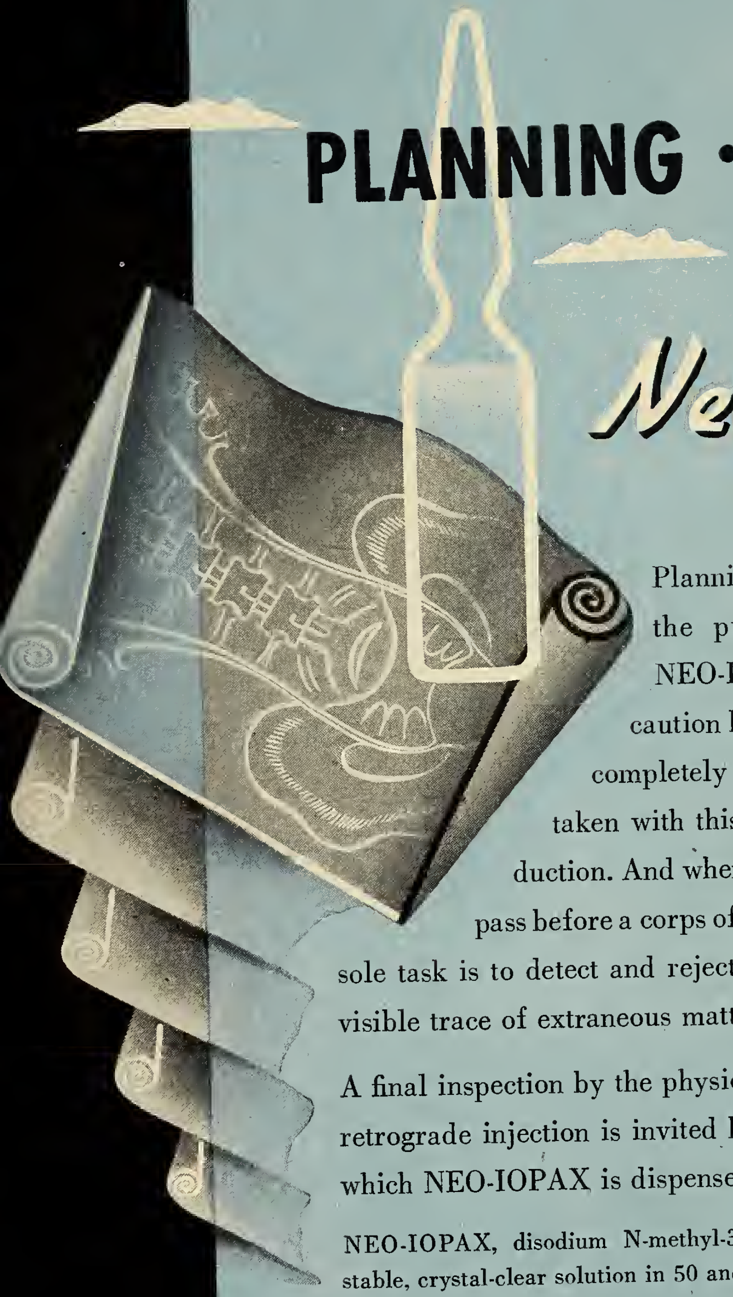
PLANNING · NOT LUCK



Neo-Iopax

ACCEPTED AMERICAN MEDICAL ASSN

Planning—not luck—is responsible for the pure, crystal-clear solution of NEO-IOPAX for urography. Every precaution known for obtaining a sterile fluid, completely free from foreign particles, is taken with this contrast medium during its production. And when NEO-IOPAX is ampuled it must pass before a corps of specially trained inspectors whose sole task is to detect and reject any solution containing the least visible trace of extraneous matter.

A final inspection by the physician himself before intravenous or retrograde injection is invited by the water-clear glass ampule in which NEO-IOPAX is dispensed.

NEO-IOPAX, disodium N-methyl-3,5-diiodo-chelidamate, is supplied as a stable, crystal-clear solution in 50 and 75 per cent concentrations.

Trade-Mark NEO-IOPAX—Reg. U. S. Pat. Off.

An Appeal to You..Doctor

SCHOOL OF PSYCHIATRIC NURSING

•

MID-YEAR CLASS
will start in
June

•

Candidates for the June class should make reservations at once. School and health record must be reviewed and correspondence completed prior to acceptance.

An acute shortage exists in the nursing field. The problem of supplying an adequate number of well-trained nurses to the medical profession has become a difficult one. *Your help in recruiting candidates for training schools is greatly needed.* In your wide acquaintance, you possibly know of many girls who could be interested in becoming a nurse. As a leading citizen of your community you are in a position to assist them in their vocational choice. *A trained nurse is a benefit to both your patient and yourself.* We are prepared to refer the student nurse back to you on completion of her training.

A Career in Nursing Offers:

- **Training in a highly paid profession**
- **A secure position unaffected by economic depression**
- **Work with skilled professional men and women**
- **The best preparation for marriage**

GLENWOOD HILLS HOSPITALS, beautifully located on the outskirts of Minneapolis, are currently offering to qualified applicants a one year course in the School of Psychiatric Nursing. All phases of the subject are skillfully presented by a capable and experienced faculty. Classroom and laboratory study is combined with an interesting program of actual work on the ward. Regular classes begin in January, June, and September.

Here is an opportunity to attain a useful higher education and still enjoy the beauty of summer to its fullest. Swimming, boating, hiking, and golf are a few of the recreational pastimes available to the student nurse. *Tuition is free.* We will be happy to send full information on request. A postcard is sufficient. Address MISS MARGARET CHASE, R.N., B.S., *Director, School of Nursing, Glenwood Hills Hospitals.*

- ***Our hospitals must be staffed***
- ***Our sick must be cared for***
- ***Our doctors must have nurses***

WHEN CHRONIC ILLNESS INCREASES THE NUTRITIONAL NEEDS

Chronic disease, whether febrile or neoplastic, imposes many additional metabolic demands upon the organism. Paradoxically, appetite is apt to wane at this time, making satisfaction of these requirements difficult. In consequence, weakness becomes excessive and the ability to resist secondary infection is impaired.

Because it contains all of the nutrients known to be essential, the dietary supplement made by mixing Ovaltine with milk can play an important role in augmenting the intake of the very nutrients needed. This nutritious food drink provides biologically adequate protein, readily utilized carbohydrate, highly emulsified fat, B complex and other vitamins including ascorbic acid, and the essential minerals iron, calcium, phosphorus. Its delicious taste assures patient cooperation, since it is taken with relish, even when most other foods are refused.

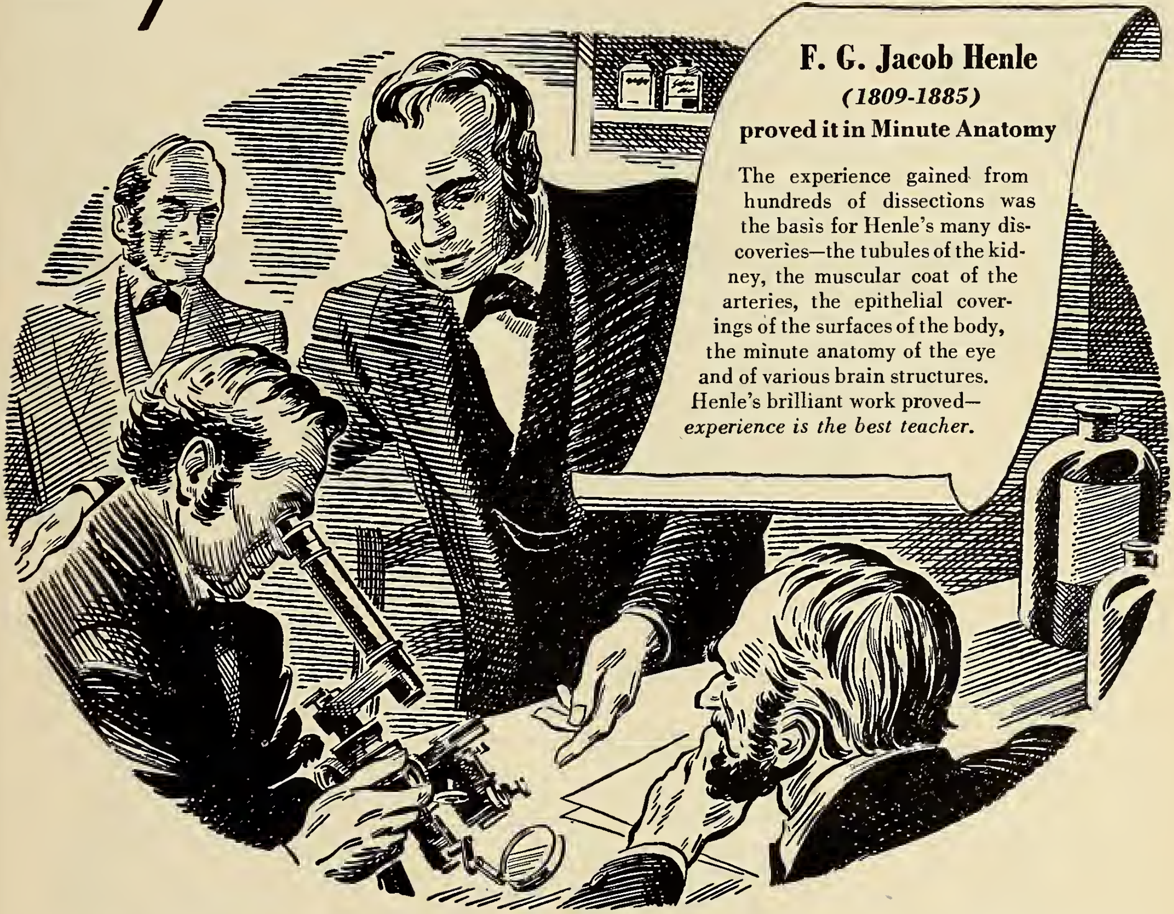
Experience is the Best Teacher



F. G. Jacob Henle

(1809-1885)

proved it in Minute Anatomy

The experience gained from hundreds of dissections was the basis for Henle's many discoveries—the tubules of the kidney, the muscular coat of the arteries, the epithelial coverings of the surfaces of the body, the minute anatomy of the eye and of various brain structures. Henle's brilliant work proved—*experience is the best teacher.*

Yes, and experience is the best teacher in smoking too!

THE wartime cigarette shortage was a real experience to smokers. Whether they intended to or not, people found themselves smoking many different brands, learning by actual experience the differences in cigarette quality.

The result of all these comparisons was the biggest demand for Camels in history. And today more people are smoking Camels than ever before. But, no matter how great the demand:

We don't tamper with Camel quality. Only choice tobaccos, properly aged, and blended in the time-honored Camel way, are used in Camels.

MADE FOR
H. W. KINNEY & SONS, INC.
Kinney
COLUMBUS, INDIANA, U. S. A.

WELL TOLERATED by the NEWBORN

Clinical experience establishes that CARTOSE* is especially well tolerated by newborn infants.

CARTOSE supplies carefully balanced amounts of non-fermentable dextrins, with maltose and dextrose. These offer the advantages of: spaced absorption because of the time required for hydrolysis of the higher sugars ; less likelihood of distress due to the presence of excessive amounts of fermentable sugars in the intestinal tract at one time.

CARTOSE is liquid; formula preparation is simple, rapid, and accurate. It is compatible with any formula base: fluid, evaporated, or dried milk.

Formulac

is vitamin-fortified

Developed by E. V. McCollum, Formulac Infant Food is fortified with all the vitamins known to be necessary for adequate infant nutrition. The McCollum procedure of incorporating the vitamins *into the milk itself* reduces the risk of human error or oversight in supplementary administration.

Formulac is a concentrated milk in liquid form. It contains sufficient vitamins of the B complex, Vitamin C in stabilized form, Vitamin D (800 U.S.P. units), copper, manganese and easily assimilated ferric lactate—rendering it an adequate formula basis both for normal and difficult feeding cases. *No carbohydrate has been added to* Formulac. It contains only the natural lactose found in cow's milk.

Formulac is promoted ethically, to the medical profession alone. It has been tested clinically, and proved satisfactory in promoting normal development and growth. Priced within range even of low-income budgets, Formulac is available in drug and grocery stores from coast to coast.

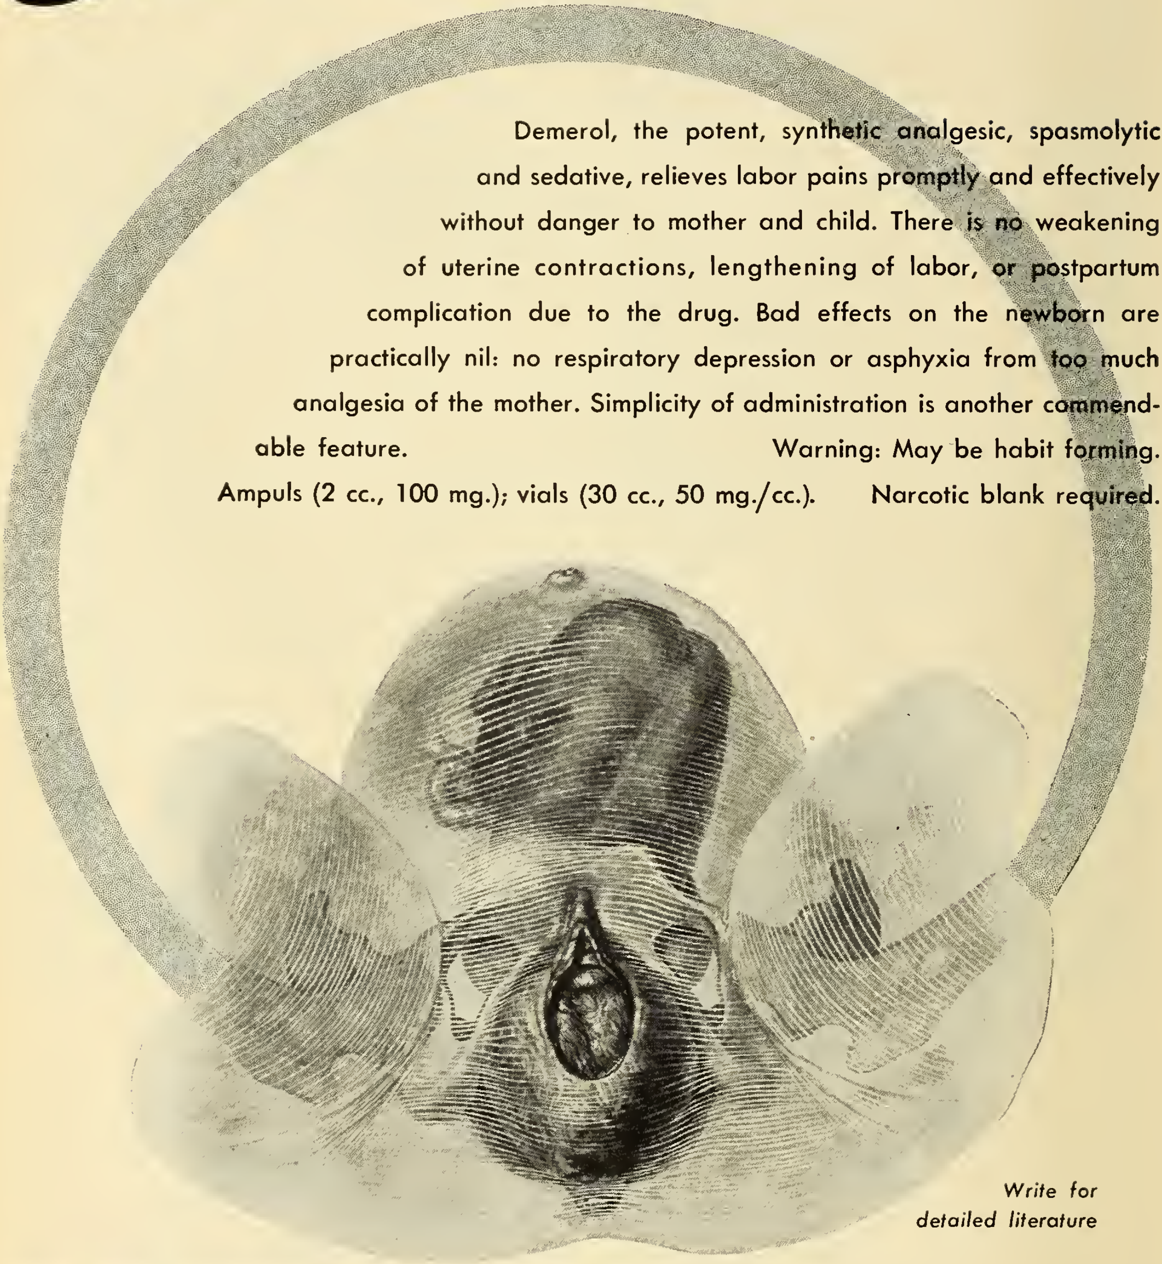
Smooth labor



Demerol, the potent, synthetic analgesic, spasmolytic and sedative, relieves labor pains promptly and effectively without danger to mother and child. There is no weakening of uterine contractions, lengthening of labor, or postpartum complication due to the drug. Bad effects on the newborn are practically nil: no respiratory depression or asphyxia from too much analgesia of the mother. Simplicity of administration is another commendable feature.

Warning: May be habit forming.

Ampuls (2 cc., 100 mg.); vials (30 cc., 50 mg./cc.).

Narcotic blank required.

diagnosis: diabetes

TODAY's newly diagnosed diabetic can live a near-normal life. Most mild or moderately severe cases can be controlled with *one daily injection* of 'Wellcome' Globin Insulin with Zinc, which also allows a higher carbohydrate intake more nearly normal. The intermediate action of Globin Insulin closely parallels physiologic needs; maximum activity occurs when the patient is awake and eating, but wanes to minimize nocturnal hypoglycemia.

INITIAL DOSAGE AND DIET: One-half hour before breakfast administer 2/3 units of Globin Insulin for every gram of sugar spilled in a 24-hour urine specimen. Or start with 15 units of Globin Insulin and increase dosage every few days.

Divide the total carbohydrate allowance (140 to 240 gms.) as 1/5 breakfast, 2/5 lunch and 2/5 supper. (The total 4/5 lunch-supper allowance may be apportioned to fit the patient's requirements.) Midafternoon hypoglycemia may usually be offset by 10 to 20 gms. of carbohydrate between 3 and 4 p.m.

FINAL ADJUSTMENT: Both diet and dosage must be adjusted subsequently to meet the individual needs. Final carbohydrate distribution may be based on fractional urinalyses. Globin Insulin dosage is adjusted to provide 24-hour control as evidenced by a fasting blood sugar level of less than 150 mgm., or sugar-free urine in fasting sample.

'Wellcome' Globin Insulin with Zinc is a clear solution, comparable to regular insulin in its freedom from allergenic properties. Available in 40 and 80 units per cc., vials of 10 cc. Accepted by the Council on Pharmacy and Chemistry, American Medical Association. Developed in The Wellcome Research Laboratories, Tuckahoe, New York. U. S. Patent No 2,161,198. Addressed to your women patients

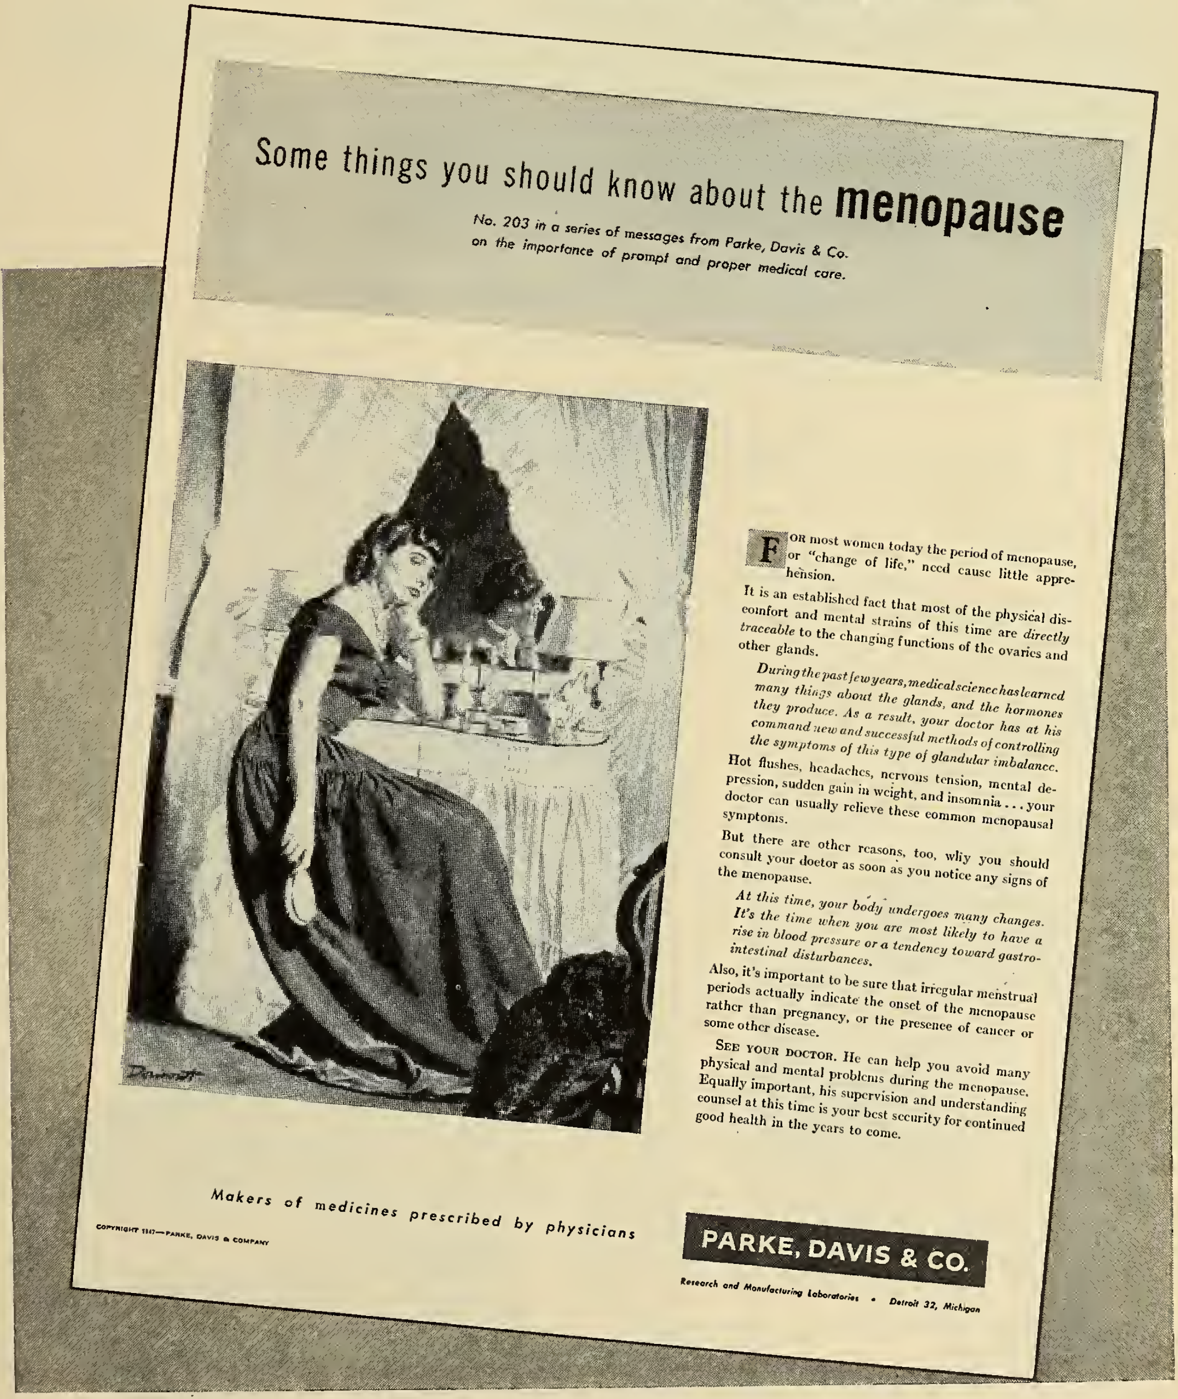
In its current "See Your Doctor" advertisement Parke, Davis & Company emphasizes the importance of seeking medical counsel at the time of menopause. This educational campaign, in behalf of the medical profession, appears regularly in color in LIFE and other leading magazines.



Some things you should know about the **menopause**

No. 203 in a series of messages from Parke, Davis & Co. on the importance of prompt and proper medical care.

For most women today the period of menopause, or "change of life," need cause little apprehension.

It is an established fact that most of the physical discomfort and mental strains of this time are *directly traceable* to the changing functions of the ovaries and other glands.

During the past few years, medical science has learned many things about the glands, and the hormones they produce. As a result, your doctor has at his command new and successful methods of controlling the symptoms of this type of glandular imbalance.

Hot flushes, headaches, nervous tension, mental depression, sudden gain in weight, and insomnia . . . your doctor can usually relieve these common menopausal symptoms.

But there are other reasons, too, why you should consult your doctor as soon as you notice any signs of the menopause.

At this time, your body undergoes many changes. It's the time when you are most likely to have a rise in blood pressure or a tendency toward gastro-intestinal disturbances.

Also, it's important to be sure that irregular menstrual periods actually indicate the onset of the menopause rather than pregnancy, or the presence of cancer or some other disease.

See your doctor. He can help you avoid many physical and mental problems during the menopause. Equally important, his supervision and understanding counsel at this time is your best security for continued good health in the years to come.

Deeds without Misdeeds

IN INTRANASAL THERAPY

Neo-Synephrine

BRAND OF PHENYLEPHRINE

HYDROCHLORIDE

If the quality of action of a nasal decongestant be the summation of its deeds and misdeeds, then the clinical response to Neo-Synephrine affirms its choice for the symptomatic treatment of the nasal congestion accompanying upper respiratory infections...

By Deed

IT ACTS QUICKLY

IT ACTS ADEQUATELY

IT ACTS LASTINGLY

Even upon repeated administration

By its Lack of Misdeeds

Neo-Synephrine generally does not cause:

- Compensatory recongestion, bogginess, atony
- Cardiac or central nervous system stimulation
- Inhibition of ciliary activity
- Blanching of the nasal mucosa

For Nasal Decongestion

Neo-Synephrine shrinks swollen nasal mucous membranes . . . relieves the hypersecretion associated with colds and sinusitis . . . is ideally suited for use by dropper, spray or tampon; for displacement; or as a jelly.

For Prescription and Office Use . . . supplied as ¼% and 1% solutions (isotonic) in bottles of 1, 4 and 16 fl. oz.; also as ½% jelly in applicator tubes of ⅝ oz.

Literature and samples will be gladly sent upon request.

3 advantages... +

1 "Premarin" ...Effective when given by mouth

2 "Premarin" ...Rarely produces unpleasant side reactions

3 "Premarin" ...Highly potent

"Premarin" provides an effective medium for the management of the menopausal patient. Prompt alleviation of distressing symptoms with comparative freedom from untoward effects may usually be anticipated with this conveniently-administered natural estrogen. To these advantages may be added the emotional uplift which is frequently reported following therapy and is invariably described by the patient as a feeling of well-being...therapy with a "plus."

The average suggested dosage is 1.25 mg. to 3.75 mg. daily. Once symptoms have subsided, dosage may be gradually reduced to a maintenance level of 0.625 mg. daily or less.

"Premarin" is available as follows:

Tablets of 1.25 mg. in bottles of 20, 100 and 1000.
Tablets of 0.625 mg. in bottles of 100 and 1000.
Liquid containing 0.625 mg. per 4 cc. (one teaspoonful) in bottles of 120 cc.

9th ANNUAL

CAMP NATIONAL POSTURE WEEK **MAY 5—10**

In its ninth year, National Posture Week continues its sound ethical program of focusing the attention of the country on the significance of Good Posture as an important element in good health and physical fitness.

Distribution of authentic literature through schools, colleges, medical and government bodies; and industrial, professional and civic public health groups is an important part of the program. Physicians, educators and lay groups in the field of public health have shown in practical cooperation and voluminous correspondence that they approve the methods of National Posture Week and its year-round program.

It is our hope that our current campaign will again merit the approval and cooperation of the medical profession.

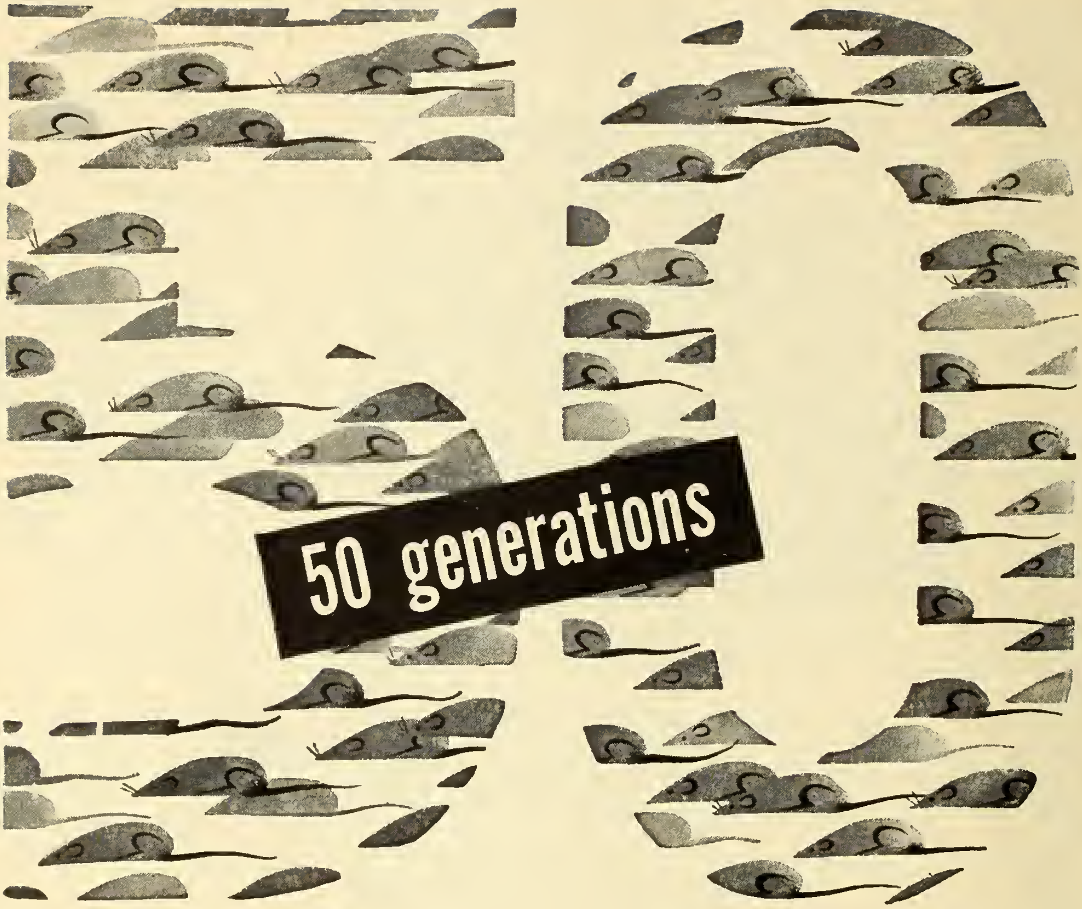
BLUE PRINTS for BODY BALANCE



When the diet of 50 generations of rats was improved, it was found that they gained a longer average life span and longer "prime of life"[1] with "increased growth and efficiency, decreased death rate and increased vitality at all ages." Without waiting 50 generations, "the size and health of our young adolescents"[2] and increased longevity[3] amply confirm the fact "that the science of nutrition has made vast strides."[2] For the present generations and those to come, Upjohn provides, and will continue to provide, the finest in vitamins, in forms and dosages to fill the needs of medical and surgical practice.

MEDICAL SERVICE PROGRAM IN THE VETERANS ADMINISTRATION HOSPITALS

GENERAL PAUL R. HAWLEY
Washington, D. C.

IN RECENT months the demands of my work have forced me to limit my speaking engagements to a minimum. I have made an exception in the case of your invitation solely because I wanted very much to come here and tell you personally how much I appreciate the support of this department of the American Legion in our effort to improve the quality of medical care given the veteran. You have been tolerant of our mistakes and patient with the slowness of our improvements. I feel, however, that you have realized that we have only one objective and that is to give the veteran the very best of medical care.

On my part, I have come to regard this department of the American Legion as an unselfish organization devoted to the true welfare of the veteran. I have never received any recommendation from the officers of your department which was in any way biased by political considerations. I congratulate you upon such leadership.

In coming here to thank you for your help and co-operation, I do not mean to imply that I resent criticism, or that I regard all criticism as an unfriendly gesture. I expect criticism—in fact, I would say that I welcome criticism. But I do hope that criticism will be well-informed, that it will be based upon fact, and that it will not be prompted by selfish or self-seeking motives.

One of the situations for which we are criticized frequently is that we do not have enough hospital beds to care promptly for every veteran who seeks admission to a hospital. This is quite true. There are several reasons for this, but the only cogent reason is that we are unable at this time to obtain a sufficient number of physicians of proper quality to operate any more beds than we are now operating. I want to emphasize this qualification of "proper quality" when I speak of physicians.

I am constantly amazed at the number of people in this country—at least, at the number who come into my office—who seem to think that a doctor is a doctor, that all doctors are equally trained and equally competent. These people descend upon me in delegations, insisting that I take over and operate a surplus army or navy hospital in their home towns. When I point out that I must have a great deal of help from local physicians, since we do not have enough full-time specialists in the Veterans Administration, they assume an injured expression and say, "Why, we have the finest doctors in the country in our town, and they would all be glad to help."

Then, when I investigate the training and the qualifications of the doctors in their town, I find perhaps one or two specialists of real training and the rest general practitioners. Now, mind you, I have no doubt but that these general practitioners are excellent as general practitioners, and I could not have any but the highest regard for general practitioners of medicine. My grandfather was a general practitioner; my father was a general practitioner; and I started my career in medicine as a general practitioner. In our hometown plan for outpatient treatment of veterans with service-connected disabilities, we shall use the services of thousands of general practitioners throughout the United States, and they will give

---

Address delivered at a meeting of the Department of Minnesota, the American Legion, St. Cloud, Minnesota, August 13, 1946.

the veterans the finest of care. Furthermore, when we general practitioners have a patient who requires the care of a specialist, we refer that patient to a specialist.

So, when a veteran needs a specialist, he must have a specialist. The great majority of hospital cases are of a severity that requires the attention of a specialist; and we would be short-changing the veteran in a shameful fashion if we offered him one kind of a doctor when he needed another kind of a doctor.

Now, here is my position. It may be wrong, but it is the position of a doctor who is concerned only with the welfare of his patients. I do not want to operate any more hospital beds than I can operate at a standard that the veteran deserves. I do not want to offer the veteran any medical service of poor quality. I much prefer to offer him none at all than to offer him some that may cost him his life or his future health. I want the veteran to feel that, when he comes to the Veterans Administration, sick or disabled, he will get only first-quality medical care. It would be an empty gesture—nay, it would be criminal—to offer the veteran *poor* medical care in order to offer him *more* medical care. We want quantity—yes—but we shall not sacrifice quality merely to produce quantity.

But a much more vicious form of criticism is beginning to arise. Our motives have been questioned in certain quarters. The program has been attacked by certain organizations. Some of these critics may be sincere, but if so, they are misinformed. However, I think the time has come to speak frankly—some of them unquestionably are motivated by selfish, personal greed.

A year ago the Medical Service of the Veterans Administration was made up of a few outstanding men in medicine, of a number of what might be called average medical men, and of some distinctly inferior medical men. As is always the case, one poor man can do more harm than ten good men can do good. So the medical service of the Veterans Administration suffered severely from the reputation given it by the poor element.

The veterans' organizations and the public were demanding improvement of this medical service. They were demanding the weeding out of incompetents. Well, we have tried to weed out the incompetents. Some of them we have dismissed. Others we have moved to positions of lesser responsibility. A doctor may be incompetent to do major surgery but reasonably competent to make routine physical examinations. As rapidly as possible, we have replaced incompetents with well-trained and able physicians, either on a full-time or a part-time basis.

Here is one curious result of our efforts to give the veteran better doctors. Some—not all, of course—of the same people, some of the same organizations, who one year ago were damning the medical service of the Veterans Administration, have now taken up cudgels in behalf of the incompetent doctors who have been replaced. They are attacking our program solely upon this ground. But—remember this—they are fighting for privileges for the doctor, not for better medical care of the veteran. I am not running this medical service for doctors—I am running it for patients—and I know no other way of raising the standard of medical care of the veteran than to replace poor doctors with excellent doctors. You can't make an omelette without breaking some eggs.

I am fully aware that, in our haste to improve conditions, we have made mistakes. We may have displaced in the service, but not removed from the service, some doctors who were better than their records indicated. We are now correcting, and we shall continue to correct, such mistakes as rapidly as we discover them. But the hard fact is that we have made more mistakes in the other direction, by not removing some doctors who should be removed. And, let there be no mistake about this, if I must commit an injustice, I would much rather commit it against a doctor than against a patient.

The fact is that no physician in the Veterans Administration of even average qualifications has suffered from this reorganization. The great majority of them were advanced one grade when they were taken into the new Department of Medicine and Surgery. None was demoted. Many of the excellent men were advanced two grades. All these actions, however, were taken with only one thought in mind, the good of the veteran patient. Again I say, we are not operating this medical service for doctors, we are operating it for the patients. No doctor has a vested right in his position in the Veterans Administration. If the doctor's services are good for the veteran patient, there is nothing too good for the doctor.

If the doctor's services are not good for the veteran patient, there is no place in the Department of Medicine and Surgery for that doctor.

Some of the criticisms leveled at this program smack of the witch-hunting of the seventeenth century. These critics say that we are using veterans as guinea pigs, that we are experimenting on them in veterans' hospitals. *Nothing could be farther from the truth.* But the worst aspect of this criticism is that these misinformed critics are being furnished their information by certain disgruntled doctors of the old regime of the Veterans Administration. *These doctors know that they lie.* And the fact that they know they lie, and use these lies in an effort to destroy a program which offers more to the sick veteran than has ever been offered to him before, is a measure of the character of these men. If you want men of this character to take care of the veteran, I and a great number of other doctors will step down gladly and turn the program over to them.

I want to make it very plain that I am not indicting any great proportion of the older men in the Veterans Administration medical service. Many of these men have hoped and prayed for years for a program of this kind. Many of them are supporting it unselfishly. Some of the older men know that they can never qualify for the additional pay of specialists; but they realize, as I do, that new standards have grown up in medicine and that, if we are to improve this service, we must accept these standards and abide by them. The fact that they have passed the age where they themselves can enjoy this extra compensation has not soured them, and they are loyally supporting our efforts. We shall eventually identify the small group of malcontents who are trying to sabotage this program. There is no place in the Department of Medicine and Surgery for a doctor who places his own interests above the interests of the veteran patient.

The most absurd aspect of this ignorant criticism is that our program is exactly like that in the most famous hospitals and clinics in the United States. These are all teaching institutions. Here in your own state stands the first, the largest, and the most famous of all the great clinics of the world. It is a teaching institution. It trains resident physicians and surgeons, exactly as we are training them in veterans' hospitals. Its clientele is drawn from all economic and social classes, millionaires to paupers. And its millionaire patients are used in its teaching program just as are its pauper patients. While I know nothing of the policies of the Mayo Clinic, and certainly shall not presume to speak for it, I would venture the opinion that it would not consider staying in business without its teaching program.

The training program in veterans' hospitals is established for the same reason that the training program was established in the Mayo Clinic, that it was established in the Massachusetts General Hospital, that it was established in Johns Hopkins Hospital, and that it was established in every outstanding hospital in the United States. The reason is that the patient gets better care in a teaching hospital than he gets in a non-teaching hospital—his case is studied more thoroughly, and the staff members are constantly stimulated to higher standards. We have this program today in thirty-two of our 107 veterans' hospitals. The standard of patient care in these thirty-two hospitals is not to be compared to the standard of patient care in the other seventy-five. Here in the State of Minnesota is a veterans' hospital that compares favorably with any hospital in the world. Here is a hospital in which the veteran is assured of receiving absolutely first-class medical care, a hospital which he can enter with confidence. I ask you only one question: has this always been true of the Minneapolis Veterans Hospital? If and when I get sick, if and when I need a surgical operation, I shall go into one of our teaching hospitals. I would enter the Minneapolis Veterans Hospital as a patient without the slightest question in my mind but that I would get absolutely first-class care. I want no veteran to have to accept a lower standard of medical care than I would accept for myself; and I shall not be satisfied with any veterans' hospital until I am willing to enter that hospital as a patient myself.

I have spoken of new standards which have been introduced into medicine within the past fifteen years. These are the standards set up by the American Specialty Boards. I shall not bore you with a detailed technical description of the functions of these Boards, but a simple explanation will help you to understand the next point I wish to make.

Any licensed physican can call himself a specialist and practice any specialty in medicine, regardless of whether he knows anything about the specialty or not. I can go back to the State of Indiana tomorrow, where I am licensed to practice medicine, and set myself up as a specialist in diseases of the eye, although I have had no training whatsoever in diseases of the eye other than the little that was given to me thirty years ago in medical school, and that, I assure you, was not very much. However, if unsuspecting patients came to my office—and they would come in greater or lesser numbers—I could treat any of their eye diseases, I could operate upon them for cataract (which is a very delicate operation), I could operate upon children for crossed eyes. If my patients were blinded as a result of the treatment I gave them, it would just be their hard luck. My license to practice medicine permits me to undertake anything in the field of medicine and surgery.

Realizing this situation, a few well-trained specialists set about doing something to protect the public from incompetent and unscrupulous physicians who were practicing specialties without adequate skill. So now, each specialty of medicine has its own examining board to test the qualifications of physicians desiring to practice that specialty. These boards require from three to five years of intensive postgraduate training in the specialty before they will even admit a candidate for examination. Then they subject the candidate to a searching examination in that specialty. If he passes, the board issues a diploma to the physician, which testifies that he has had adequate training in his specialty. While this diploma has no standing in law, the patient is protected against quackery if he employs only specialists who are diplomates of their respective specialty boards. I must make it perfectly clear, however, that not all well-qualified specialists are diplomates of their specialty board. Some of the older men, who had been practicing a specialty for years before the boards came into being, never bothered to obtain certification. However, almost all of the younger men who are entering specialties make a serious effort to obtain their board diplomas.

You can understand how difficult it is to obtain such a diploma, and how much better trained, on the whole, these diplomates are. In the old regime of the Veterans Administration, there were only approximately sixty diplomates of American Specialty Boards in the medical service, and these were largely x-ray men and laboratory men. There were only a very few in the fields of internal medicine and surgery.

Since, January 3, 1946, on which date the President signed Public Law 293, we have employed full-time and placed on duty in the medical service of the Veterans Administration, 150 additional diplomates of American Specialty Boards—the cream of the profession, the *corps d'elite* of medicine. Never before could this service boast of such a large group of experts. We have more than doubled our number of expert specialists.

But this is not all. Among these men are many who have held positions of distinction in the world of medical education. I shall quote from only a few of their applications for appointment in the Department of Medicine and Surgery: professor of surgery, University of Illinois; assistant proessor of medicine, Johns Hopkins University; professor of clinical surgery, Women's Medical College of Philadelphia; assistant professor of medicine, University of Pennsylvania; assistant professor of surgery, University of Maryland; associate professor of medicine, Wayne University, and many more. I want to emphasize that these men are now full-time doctors in the Veterans Administration. In addition, we have several hundred diplomates of American Specialty Boards who are daily giving part-time service to the veteran.

How many men of this professional stature do you think would have come with us under the old regime? What is it that now attracts such able physicians to the Veterans Administration? It is just two things. First, they believe that this service is now free from politics and that they can practice real, honest medicine. And second, they desire the opportunities we have made for them to teach medicine. Most of the outstanding men in medicine love to teach, and 95 per cent of these outstanding men would never have considered the Veterans Administration as a career without the opportunity to teach and to train younger men.

Now, just what is the teaching program in veterans' hospitals? From the criticism leveled at us from certain sources, one would think that we were undertaking the training of first-year medical students. The fact is that our residents in training are all graduates of Class A schools of medicine, that they have completed their internships and that they are fully licensed to practice medicine. They are a standard of physicians that the Veterans Administration would have been extremely happy to employ in years past.

There are only two ways by which a doctor can perfect himself in a specialty of medicine. One is for the doctor to train himself—by trial and error. This may result in good training after some years of what amounts to experimentation on patients, but it is rather tough on patients until the doctor acquires some degree of competence. Many of the older doctors in the Veterans Administration trained themselves in this way, because there was no other way for them to get training.

The other way is for a doctor to work under the guidance and direction of an expert in the specialty—an expert who teaches him, who prevents him from making mistakes, and who does not permit him to touch a patient until it is evident that he is competent to undertake some small part of an operation. For three years he works under the direct supervision of the expert, and there is no experimentation upon patients with this method.

Which method do you prefer? Do you want to be cared for by the doctor who is teaching himself, or do you prefer the doctor whose every step is being supervised by an expert?

Thus, these resident physicians in training in veterans' hospitals are exactly the kind of doctors that the Veterans Administration would have been happy to have employed in times past. But what would have happened if they had been employed in years past? The majority of them would have been placed in full charge of the treatment of patients, with little or no supervision, and with little or no instruction. Many of them would have groped their way into the specialties of medicine. Today, these same young men work under the close supervision of highly qualified specialists. They are guided and trained. They are not permitted to make mistakes. Which of these systems do you think results in the better care of patients?

I am making no apologies for the new medical program of the Veterans Administration. No apologies are necessary. It has been given the enthusiastic approval of the leaders of American medicine. The only question is whether you want to believe medical men of national reputation or a few disgruntled doctors who have a purely selfish interest in jobs with the Veterans Administration.

Whether I remain in my position is of no importance. I accepted this position, and have remained thus far, at a very considerable financial sacrifice. The best thing that could happen to me personally would be that I am driven out of this position. I cannot, in conscience, resign so long as there is hope to give the veteran the best in American medicine, but I can always be fired.

I do hope, for the sake of the veteran, that there is never any return to the medical service of the past. Who operates this service is of no importance whatsoever. But *how* it is operated is of the most vital importance to the veteran.

AT LEAST, NOT YET

We think it was de la Rouchefoucauld who said, "There is always something in the misfortunes of our friends that does not quite displease us."

This morning, after we had brought ourself abreast of the latest developments in the labor situation; after we had mastered our nausea over the statistics of lowered production, decreased exports, et cetera, that would result, we turned to foreign news in the hope of finding something cheerful.

In no time at all we came upon this gem:

London, November 30. (UP)—Sixty-four doctors and nurses—the entire medical staffs of two London hospitals—have received dismissal notices for refusing to obey an order of the Willesden Borough Council to join a trade union, it was disclosed today. The Council's action leaves only one doctor, the medical superintendent, to care for 100 patients at Willesden Maternity Hospital.

Socialized Medicine! The closed shop applied to doctors. We are a little vague as to what the Borough Council of Willesden is, but somehow we feel a little safer with our mothers and babies in the hands of medical men selected by Boards of Trustees. We are glad we don't have to join a union if we don't want to.

Oh, and by the way, what happens to the mothers and the babies? The Council bent on asserting its authority seems as indifferent to their fate as Mr. Lewis was to the general suffering he was causing.—New York J. Med., Feb. 15, 1947.

VOLUNTARY PREPAYMENT MEDICAL CARE AND ITS RURAL ASPECTS

LOUIS A. BUIE, M.D.
President, Minnesota State Medical Association
Rochester, Minnesota

IN this presentation I shall use the expression "medical care" to mean those services which usually are represented in the doctor's bill. Medical care, then, is distinct from hospital care.

Voluntary prepayment medical care dates back to 1882 but its expansion is relatively recent. This expansion began in Washington and Oregon shortly after World War I as an effort designed to overcome some of the undesirable features which existed in contract practice. Little was done elsewhere during the next ten years. With the depression came interest in ways and means of assisting people in what we then called the "low-income" or "borderline" groups of the population. In order to assist people of these groups, experiments were carried on with many plans. State medical associations, county medical societies, the Farm Security Administration (now the Farmers Home Admistration) and others studied and experimented with prepayment and postpayment ideas.

Prepayment plans today can be divided into three groups: service plans, indemnity plans and a combination of the two. In the service plans the fee or rate paid by the organization to the physician constitutes the entire amount which either the organization or the patient will be required to pay for the service. This was the general pattern of the early plans and of those born of the depression.

In the indemnity plans, the patient is paid a prearranged amount for specified medical services or care. The patient is responsible for paying the physician. The physician charges the patient according to his own fee schedule. The charged fee may be more or less than the amount paid by the organization to the patient and is generally determined by the physician on the basis of the patient's ability to pay. Up to the present time, the indemnity plan usually has not been the pattern preferred by physicians but sometimes is the only avenue open in forming an organization.

In the third type of plan, the patient whose income is below a certain level receives service benefits and the patient whose income is above this level receives indemnity benefits. Usually these levels are set at $1,000 to $2,000 a year for single persons and at $2,000 to $3,000 for families. This is probably the most popular plan today.

The movement toward prepayment plans actually received its first real impetus as a result of the achievement of the Blue Cross Hospital Service Plans. With both hospitals and patients in dire need of some sort of program to ease the burden of costs of expensive hospitalization, these plans spread quickly.

With the prepayment plans for hospital charges as guides, a number of state medical associations undertook to develop plans for medical care. The first state-wide plan to be put into operation was California Physicians' Service. This was followed within a year by Michigan Medical Service. These two plans, together with the county medical society bureaus of Washington and Oregon, gave the medical profession the necessary basis on which to build what has now become a nation-wide movement.

Growth

Counting Oregon and Washington plans as two state-wide plans, the growth of prepayment plans for medical care since 1939 has almost paralleled that of the hospital plans. It took Blue Cross between five and six years to place thirty-eight plans in operation. This compares favorably with the six years it took to develop thirty-seven plans for medical care. The same comparison also can be made with reference to enrollment. In medical plans, 2,845,000 subscribers were enrolled from 1929 to 1946. In Blue Cross plans, 2,870,000 subscribers were enrolled from 1932 to 1939.

In some ways, the achievements of the medical profession in developing its own prepayment program are remarkable. The problems involved in the payment and handling of claims for medical services are far more difficult than those for hospitalization. It took years of experimenting and compromising to work out solutions, but the progress made to date offers its own proof that advancement has been made.

Read at the annual Delegate Meeting of the Minnesota Farm Bureau Federation at the Lowry Hotel, Saint Paul, January 13, 1947.

An organization to pay for hospital care deals with relatively few institutions. A plan designed to pay for medical care deals with hundreds, or even thousands, of physicians. Physicians are anything but institutions. They are individuals and, as a practical administrative matter, a plan for medical care must not depend on a relatively uniform institutional point of view but on a host of individual attitudes, if the principles of the private practice of medicine and high quality of medical care are to be retained.

The latest figures show that eighty-four prepayment plans for medical care have been approved or sponsored by medical societies and the Blue Cross. Organizations are now in operation in thirty-three states, and, in addition, are being formed in thirteen states and the District of Columbia. In only two states is no plan for prepayment for medical care in process of development.

From some sources you may hear that the principle of voluntary prepayment has failed, that prepayment plans have not measured up to the demand of the public. These are unwarranted claims. The fact that not one of the prepayment plans developed by medical societies has failed since 1939, plus the fact that only two states remain in status quo, attests to the fact that efforts sponsored by organized medicine thus far have not failed. However, there is still much to be done.

Method of Expansion

Here are two avenues for expansion in the program for prepayment for medical care. The first refers to benefits (in the form of services, indemnities or both) that can be offered in view of fees paid and premiums charged. The second refers to subscribers and to enrollment.

Let us consider each of these avenues separately for a few moments. The expansion of benefits is limited partly by insurance principles; that is, by the amount of the premium, dues, or whatever the income is called, that can be collected. In other words, the benefits cannot exceed what the public will or can pay for.

In the early plans in use in Washington and Oregon, these benefits included practically all medical services: surgery, home and office calls, and even limited nursing and dental care. Through the years since these plans were inaugurated, this broad coverage has been continued. The plans organized in 1939 and 1940 followed this lead and also provided for reasonably complete medical care. In contrast, in later plans full coverage has been demonstrated to be unsatisfactory. It was found that the public would not or could not pay the premiums necessary to carry such a broad contract. Wherever a contract for surgical care and a contract for general medical care were offered, the ratio of enrollment was more than 100 to 1 in favor of the surgical program. As a result, the plans generally have preferred to begin by offering fairly restricted coverage, including such items as surgical care, obstetrical care, x-ray charges, and fees for anesthesia, all applying only if the patient is hospitalized. Then, as experience was obtained, benefits were added. The latest development has been the addition of medical service in the hospital. Now most of the services necessary in cases so severe as to require hospitalization are covered.

The tendency to limit services to those accorded in the hospital is a natural one. In the first place, most of the costly illnesses are those that require hospitalization for the patient. Second, there is likely to be little abuse of such services. Third, actuarial experience with relation to hospitalized patients is sufficient to provide more certain bases for determining adequate premiums or rates than are available with respect to patients seen in their homes or at offices of physicians. A recent study of fifty-one plans for medical service shows that thirty-four offer surgical, obstetrical and specified medical services in the hospital. This same study shows that under some plans benefits are continuing to expand. In twelve of the plans, provision is made for general medical care such as home and office calls and, in five, almost complete coverage is provided.

The average monthly premium for a single subscriber is approximately $1.25 and ranges from as little as 60 cents to $4.85. Family coverage ranges from $1.35 to $10 a month, with an average of about $3.

Organizations are still experimenting with benefits and with premium rates. As in one organization success is attained with some new idea, it is made available to other organizations. The same, of course, is true of failures. In this manner, expansion or retrenchment will continue as actual experience and public demand dictate.

Here in Minnesota it is expected to offer, at the outset, something about midway on the scale just described. By this I mean that it is intended to offer more to the subscribers than just surgical care or medical care while in hospital but less than full coverage. The contract as finally agreed upon probably will provide for limited general medical care (home and office calls) and certain special medical services.

This is the intention because it is believed that our need in Minnesota is somewhat different from that in the highly urban areas where most plans have started. In our state, about 50 per cent of the people live on farms or in small towns and villages. It is necessary to offer these people a contract under which they will be provided with reasonably adequate medical services. Experiments in rural areas have, of course, shown that the rate of utilization is higher than in cities. The financial risk is greater. Where workers are not covered by workmen's compensation insurance, all injuries and illnesses automatically come within the scope of a prepayment plan.

The success of a plan under which general medical coverage is offered depends on two things, namely, control of abuses and adequacy of premiums. Abuses may be perpetrated by the physician or the subscriber. It is the duty of the medical profession to keep its own members in line. So, too, it is the duty of enrolling groups, whether they are drawn from factories, farms, or towns and cities, to keep tab on their members. The same sort of fifty-fifty responsibility plays a part in determining premiums. What can the subscribers pay; what must be charged if the organization is to remain financially sound? I have mentioned that before, and have given some figures. I mention it here again because it has an obvious bearing on what I propose to take up next, namely, the second of the two avenues for expansion and what its limitations are.

Expansion of the program of prepayment for medical care is limited then partly by the ability and willingness of the public to enroll as subscribers. Most of the plans have been applied in urban areas where large enrollment was possible. This was a sound method because the sooner an organization obtains adequate spread of its risks, the sooner it can expand its program of benefits and enrollment. Large enrollment provides this spread much more easily and quickly than small enrollment. Not only this, but the cost per subscriber is lower if enrollment is large than if it is small.

The pattern is now changing. Nearly every organization which has reached reasonable enrollment and a sound financial level is turning to ways and means of reaching all groups of the population, particularly rural groups.

In general, the pattern has been to deal with the farm group not as a separate entity but to include it in what is called "community" enrollment. In community enrollment, the farmer is included with the residents of a city, town or village near which he lives. Usually the town is a center for banking, a source of supplies and so forth. The whole community then composes the group, and premiums are payable at a central place.

A successful Blue Cross enrollment campaign in rural areas was carried out by the Weld County, Colorado, Agricultural Health Association. Enrollment was on a community basis, reaching all elements of the community as a civic service. Weld County, the largest county in Colorado, is about three times the size of Rhode Island and boasts a population of 63,700. Greeley, with 15,900 residents, is the largest city in the county. There are several smaller towns, the largest of which has a population of 1,800. Prominent businessmen, leaders of farm organizations and various club leaders met with Blue Cross representatives and decided to form a health association under the Colorado law governing co-operatives. Twelve directors, each representing a definite district in Weld County, govern the health association. This division provided units that were workable as to area and population for an enrollment and administrative program. Enrollment was not limited to Blue Cross but each district was allowed to enroll separately in the Colorado Medical Service plan whenever 50 per cent or more of the families in the district had subscribed to the health association and to Blue Cross. Experience demonstrated the value of a paid secretary, to work full-time with the voluntary committees; also to keep the records and to handle the billing. The secretary's salary and other necessary expenses were financed by an annual charge of $1.00 per year assessed against each member who was more than eighteen years of age. To date, Weld County has 8,000 enrolled. In Colorado, ten similar county health associations have been organized, and one of every six persons in rural areas and one of every two urban residents have been enrolled.

In Iowa, fifty-five similar county health improvement associations have been organized. In other states enrollment on a similar community basis is taking place although organization is less formal.

Although the foregoing does not apply solely to medical plans, voluntary prepayment medical plans are making rapid progress in rural areas. The problem cannot be solved on a national level. It must be worked out in the community where the need exists. Everyone in the community must lend support if any effort is to succeed.

Continuing improvements in transportation will accelerate the growing tendency of rural people to bring the patient to the physician. Thus, physician's care and other health facilities can be extended over an area that will include a sufficient number of people to meet the costs of the services provided.

The fees for medical services rendered by rural practitioners are not excessive. However, there are times when illness strikes and the severity of the case cannot be predetermined. For this reason, many farm families faced with severe illness find it difficult to meet the full costs when illness does strike. This problem is basically the same as it is with people living in towns.

Medical Care for All

The medical profession has felt that it has done well to charge for its services on the basis of the patient's ability to pay, charging nothing at all in many instances and thus excluding nobody from medical care. But this method is not agreeable to everybody concerned nor is it certain that it will prove sound in a future of unknown stresses. The only sound method so far devised to provide medical care for everybody in a free society is through use of the insurance principle. Prepayment plans for medical care available to all people of a community, townspeople and farmers alike, tend to spread the risk and distribute the costs. Thus, having the cost known in advance, proper planning and budgeting for the otherwise unpredictable costs of illness are possible.

Physicians, because of their special training, will bear the responsibility for the professional aspects of the program. They also will see to it that fees are not higher than they should be. The recipients of medical service cannot escape the responsibility of paying the cost of the services. Both parties to the contract should do their full share in providing the needed facilities.

For ten years or more physicians have operated organizations under pilot plans for insurance against the costs of medical care. From this experience they now feel that they should recommend prepayment plans. Thus, the American Medical Association enters the picture. This association is not a superior authority which issues orders to its state and county units. It is the recipient of, and gives expression to, decisions reached in the county and state units. These units have caused to be formed a Council on Medical Service of the American Medical Association and one of its chief functions is to help in the development of prepayment plans in various communities. The state medical associations and the American Medical Association have rural health committees devoting their attention to the rural problem.

As has been said, physicians are co-operating in local efforts and also are making available prepayment plans of medical societies so that everyone interested may have an opportunity to insure himself against medical expense. Local representatives of farm organizations, business groups and local medical societies working in full co-operation and understanding are now in a position to work out the difficult economic problem of delivering medical care to all the people.

A Qualification

In closing, may I say that the assignment to discuss this subject was accepted with full realization of the vastness of the problem.

At the height of ancient Greek culture, there were said to be only seven philosophers who knew the truth; everyone else was ignorant. Today many of us believe that we alone know the truth. How many are there who, like Socrates, will admit that all they know is that they know nothing?

Aristotle remarked that everybody contributes something to the truth but no one person can apprehend it by himself. No mortal is ever entirely right.

THE TREATMENT OF PERSONS WHO HAVE BRONCHIAL ASTHMA

ARTHUR T. LAIRD, M.D.
Duluth, Minnesota

ASTHMA is a Greek word which means shortness of breath, or panting. In English it has come to mean severe dyspnea, which may occur in a variety of conditions. We speak of bronchial asthma and of cardiac asthma, but used in this way it is merely the name of a symptom.

The word is quite generally used to denote bronchial asthma alone, that is to represent the definite clinical complex exhibited by certain patients who between periodic attacks of wheezy dyspnea are to a large degree subjectively and objectively well. Even used in this sense it is not really the name of a disease. While ordinarily the symptom complex can be recognized without too much difficulty, the diagnosis of its exciting cause and the underlying constitutional basis should also be made.

A patient suffering from an attack of bronchial asthma is having a form of shock, somewhat similar to the anaphylactic shock which occurs in experimentally sensitized animals. Admitting the occurrence of such paroxysms on a nonallergic basis and of their development without previous protein sensitization or exposure to allergens other than bacteria within the patient's own body, it is still generally agreed that bronchial asthma in most cases is a clinical manifestation of an allergic diathesis which the patient has had since birth and which he has inherited.

Adequate diagnosis requires not only that the character of the paroxysm be recognized, and if possible the exact nature of its exciting cause, but for successful treatment it must be constantly kept in mind that there is also present an underlying constitutional state.

In no condition is it more necessary that the physician who hopes to benefit his patient permanently become thoroughly acquainted with him as an individual, know his antecedents and continue in close touch with him throughout his entire life.

Persons who have bronchial asthma are thus different from other people. They nearly all belong to a definitely allergic group which is said to comprise from 10 to 15 per cent of our population, and for the most part they are born with a predisposition to develop asthma or some form of allergy.

That the tendency to become sensitized is transmitted according to the Mendelian law as a dominant characteristic was shown by Cooke and Vanderveer in 1916.

Asthma may be more or less of a handicap in accordance with the frequency and severity of the paroxysms as they occur at intervals during a longer or shorter life. The patient's titre or measure of sensitiveness to this particular allergen or *bete noir* varies in different individuals and is not always at the same level in the same individual. There are many predisposing causes which may lower it, and it is well worth the patient's and physician's time to seek them out and avoid them. It is the tendency, not the specific sensitivity, that is inherited. Persons inheriting such a tendency are handicapped as truly as those who have lost an eye or a limb. The main underlying cause of asthmatic seizures is this bad family history. It is peculiarily unfortunate if both father and mother are asthmatic or even allergic to the extent of being sufferers from hay fever or other definite manifestations of allergy. A child born in such a family needs special watchfulness on the part of his parents and his doctor. The acquirement of an inferiority complex is an incidental handicap which awaits many such children, even if they do not develop allergic symptoms.

Many superficial observers will feel that most asthmatics are neurotics and will look for a psychoneurosis to explain their sufferings, but scientific analysis has never been able to prove that asthma is a neurotic or hysterical reaction.

A mental element was suspected in the case of one of our patients who had been driven by her distress to long journeys and strange behavior. Meanwhile, her children had to travel with her, and their surroundings and experiences were not those included in a child's bill of rights.

This young woman, in 1936 before her marriage, when twenty-two years of age, was doing housework in Minneapolis and contracted a severe cold. Since then she has had asthma more or less continuously. Meanwhile she married and she has had three children. She was in several states and various hospitals while her husband

---

Read before the medical staff of St. Mary's Hospital, Duluth, Minnesota, October 3, 1946.

was in the army. Though a resident of Stearns county, Minnesota, she came to Duluth in 1944 and expected to remain here indefinitely on account of the climate. She has had skin tests and was found to be allergic to feathers, dander and certain foods, and was given various treatments, including sinus surgery and removal of nasal polyps, but when she arrived here she was thoroughly convinced that climate and intravenous injections of aminophyllin were the only things that could help her. In fact, she was addicted to the intravenous use of aminophyllin. Admitted to St. Mary's Hospital on July 22, 1944, she received intravenous injections of aminophyllin at frequent intervals, sometimes several times a day. She remained in the hospital nearly two months, getting various other medicines and treatments as well. Among them was potassium iodide.

On November 19, 1944, when she consulted the Duluth Clinic, she was the picture of distress. This appearance was accentuated by an extensive acne of her face, and she again received temporary relief through an intravenous injection of aminophyllin. Later the same night she appeared at the emergency room at St. Mary's Hospital and asked for another intravenous injection. This sort of thing continued for several days and nights and kept the interns busy, until four days later she was admitted following an early morning emergency injection of aminophyllin. She had received fifty-nine such injections in the previous six weeks. In the hospital she received more aminophyllin injections. The paroxysms of dyspnea, for which she sought relief were likely to occur at most inconvenient times, often when the nurses were busy with meals and interns were difficult to secure. She seemed such a difficult and unreasonable patient that she was transferred to the psychopathic ward, but the psychiatrist who was consulted reported that her actions and deportment were typical of one suffering from a chronic medical condition and were due to introspection, anxiety about herself and her problems, rather than any psychosis.

She was then removed to another ward and the situation was explained to her as well as could be. There she received intelligent and tactful care from the interns and nurses and was asked to co-operate as far as possible. Gradually she became less apprehensive, and acquired some faith in intramuscular and rectal injections of aminophyllin, and before discharge was relieved by adrenalin. Later when she was admitted to St. Luke's Hospital in a temporary panic, the same program was followed. After a two-weeks stay she was transferred with her children to St. Cloud in an automobile, attended by a nurse. During the trip she was entirely free from symptoms. A year later the Stearns County Welfare Board reported that she and her children had left some time previously for the Southwest, either to join her husband or to search for a better climate. That there was an anxious mental state which added to her difficulties seems apparent. If she had been endowed with a different temperament her treatment would perhaps have been simpler. A great deal of her distress was certainly from apprehension.

We had another patient whose dominant idea was that he could not exist without oxygen. After hundreds of dollars had been spent for its constant and continuous use in St. Luke's and Miller Hospitals, since he evidently was a very sick man, the intern and the medical and nursing staff finally succeeded in weaning him from his dependence on it without doing him harm.

The other members of the family of one of our patients were thoroughly convinced that their mother's asthmatic attacks were largely nervous in origin and that she could avoid them by using her will power. This attitude on their part made her lot especially difficult and unhappy. She was undoubtedly neurotic. However, her neurosis did not cause her asthma, but on the contrary, was to a large extent caused by it.

Worries about financial and family affairs may also seriously depress the patient's threshold to allergic reaction. Marital difficulties have been complicating and unsolved problems in several of our cases. While the avoidance of mental disturbance is necessary in the treatment of the asthmatic, the maintenance of the best possible conditions for general bodily health is equally as important.

This has recently been emphasized by Dr. Francis M. Rackeman. Depletion of vitaliy can only lower the patient's threshold to reaction and make it possible for his latent or subclinical allergy to express itself. There is a group of patients consisting mostly of children and young adults who have asthma in isolated attacks, each attack following a new cold. Such attacks may sometimes be brought on by simple fatigue. In such cases, besides the avoidance of known allergens, improvement of the general health of the patient is most important. Better hygiene regulation of his daily life, the time and quality of meals and daily activities, the institution of adequate periods of rest, fresh air and exercise, the use of extra vitamins and vaccines, are all helpful measures.

Some allergic persons living a well-regulated life are not much handicapped by asthmatic attacks. One of our patients was a boy of seventeen who had asthma for several years. He developed a severe attack on October 12, 1944, and was admitted to St. Mary's Hospital where he secured relief from adrenalin. He was quite thoroughly studied and found to have sinusitis and to be quite sensitive to various dusts, but not to foods. No surgery or change of climate was advised nor was his school work interrupted. He was simply asked to secure nine hours sleep if possible and to follow a slightly limited regime. He also took an oral cold vaccine. Careful hygiene, rather than the vaccine, was probably responsible for the fact that he had no colds during the following winter. Early in the summer of 1945, although he was frank in telling of his asthmatic history, he was accepted by the navy. In June of 1946 his mother reported that he had been in the navy a year, part of the time being spent at the Great Lakes Training Center in Illinois and part of the year in New Orleans, but that he had had no recurrence of asthma.

It will often be found that an asthmatic paroxysm has been preceded by a period of poor general health during which the patient has been below par. He may have had pneumonia, or an operation or just an upper respiratory infection. Often enough he has gone through a serious emotional experience and as a result has lost appetite and sleep. He needs an "ordered life" without "strain or stress" to keep the threshold of his sensitivity low enough to prevent the occurence of explosive reactions. "Debility" and "depletion," to use Dr. Rackman's terms, often cause them.

Getting acquainted with an asthmatic patient involves very careful history-taking to bring out underlying accessory causes which precipitate distressing episodes. Experience has shown, according to Unger, that in almost every severe case of asthma someone has been neglectful. The physician is not consulted often or retained to be a life counselor or guide to his patient, who muddles along or is neglected by his parents and friends until a violent reaction occurs, at which time they cry vociferously for help.

Hospitalization for a short time is often a wise measure since it changes the patient's environment, aids in the more exact determination of his susceptibilities, and raises his reactive threshold to offending allergens. Unless fundamental study and care is given, the patient is readmitted again and again, or else remains at the hospital for an indefinite period. One Duluth patient remained hospitalized for more than a year; another has been admitted nine times in the past two years to the same hospital.

Whatever the offending allergen may be that precipitates the asthmatic attack, the explosive reaction that occurs is substantially of the same nature in each case.

There is practical agreement that asthma patients have, in the mucous membrane lining the bronchial tubes, sensitized cells containing antibodies that are specific for certain allergens. When the specific allergen comes in contact with these antibodies in the sensitized cells in the bronchial mucosa, whether it reaches them through the inhalation of air containing it or by way of the blood stream, the reaction occurs. The severity of the reaction depends on the degree of sensitivity of the cells and the amount and character of the allergen. The bronchi containing the sensitized cells are the trigger area, and their degree of sensitivity may be so great that the most trifling circumstances, given any exposure to the antigen, may cause the explosion, even in some cases the passage from a sun-warmed area into the shadow.

As in anaphylactic shock there is narrowing of the lumen of the bronchial tubes by the outpouring of mucous which partially fills them, and probably also by muscle spasm in the smaller bronchi. The patient becomes more or less short of breath, begins to wheeze, and has a moderate amount of cough and expectoration. In more severe attacks the dyspnea becomes extreme and all the accessory muscles of respiration are brought into play. Tachycardia and sweating occur. The individual is utterly miserable, just as he has been before and is in many cases destine to be again and again.

As in surgical shock, a toxic histamine-like substance is believed to be set free which initiates the profound local and systemic reaction. The distribution of the blood is altered and its control changed. Internal secretions, especially adrenalin, are called into the circulation and various biochemical changes promptly occur, including increase in the hydrogen ion concentration, all of which have their effect on the control centers in the medulla. Fear and emotional shock are accompanied by somewhat similar phenomena.

The purpose of the emergency treatment of asthma is to interfere with the mechanisms producing shock and to lessen its severity.

The diagnosis is usually not difficult and in most cases has already been made. The wheezy dyspnea is characteristic, the long history of recurring paroxysm with no evidence of disease between the attacks makes confusion with the dyspnea of heart disease or pneumonia unlikely. However, as has been said, "All is not asthma that wheezes," and laryngeal affections, extrinsic and intrinsic lesions of the trachea and bronchi, foreign bodies, diseases of the heart and lungs, Loeffler's syndrome and functional air hunger all have to be considered.

The following summary has been prepared for me by Sister Loretta and the record librarians at St. Mary's Hospital in Duluth. It is concerned with admissions to that hospital in 1944 and 1945. Nearly every general practitioner and internist on the staff was represented among the thirty-eight physicians in charge of the patients.

As a rule, the procedures used to control the patient's paroxysms and relieve his distress were the usual well-recognized or recently publicized methods, which it may be worth while to review here.

The purpose of the emergency hospital treatment of asthma is, as has been stated, to interfere with the mechanism producing the shock and to lessen its severity. A number of medicines and measures have been proved to be helpful for this purpose in Duluth as elsewhere.

Adrenalin.—The most commonly used and most effective medical treatment of the paroxysm is the subcutaneous or intramusclar injection of adrenalin. A dose of .35 c.c. of a 1:1000 solution in normal saline may control the attack for a time varying from minutes to hours and often is as effective as a larger dose. The smaller dose can be repeated at half hour intervals if necessary. Adrenalin is of no value given orally and is rarely used intravenously. It must be used with some caution in those with hypertension and heart disease. If the usual saline solution is not effective, adrenalin may be given as a 1:500 suspension in peanut oil by intramuscular injection, in which case its action is somewhat slower and more prolonged. The inhalation of a still stronger watery solution, 1:100, from a special nebulizer, helps many patients. Some chronic asthmatics require or demand as many as ten or more injections of adrenalin in one day. The relief obtained by a single injection may in other cases last for weeks or months.

If the usual saline solution is not effective, adrenalin may be given as a 1:500 suspension in peanut oil by intramuscular injection, in which case its action is somewhat slower and more prolonged. The inhalation of a still stronger watery solution, 1:100, from a special nebulizer, helps many patients. Some chronic asthmatics require or demand as many as ten or more injections of

adrenalin in one day. The relief obtained by a single injection may in other cases last for weeks or months.

After a time, especially in the severe and protracted cases, the patient may become adrenalin-fast, a condition which however is usually not permanent.

When the patient's sensitivity to his allergen remains low and his attacks are mild, they may be relieved by the use of ephedrine, a drug whose effect is similar to that of adrenalin. It has the advantage that it may be given by mouth. There are a dozen or more preparations, each highly recommended by the manufacturer as effective in asthma, which consist of ephedrine combined with phenobarbital aminophylin or other substance. The patient may take such tablets three times a day or when needed to control an attack. If his attacks come in the night, he may take an enteric-coated tablet in the evening which becomes effective some hours after it is taken. Several of our patients have found the occasional or continued use of such tablets, together with hygienic measures, all that was required to keep them fairly comfortable for long periods.

Adrenalin was used in the treatment of nearly every asthmatic patient admitted to St. Mary's Hospital in Duluth in 1944-1945. Ephedrine, usually in combination with phenobarbital, was a supplementary medication routinely prescribed.

Aminophyllin.—When patients cease to be relieved by simple medication or by the use of adrenalin, it becomes necessary to employ other means to lessen or banish their distress. Theophyllin ethylenediamine, or aminophyllin, as it is commonly termed, is a valuable synthetic xanthine derivative. Used intravenously it promotes prompt relief in most cases. It must be given slowly to avoid causing syncope. In order that it may be injected slowly it is nearly always given in a considerable amount of saline solution. The usual dose is 0.48 gm. (7½ gr.) in 20 c.c. of normal saline solution. Sometimes 0.24 gm. (3¾ gr.) in 10 c.c. of normal saline solution is sufficient to give relief. Aminophyllin is said to act by inhibiting bronchospasm through direct action on the bronchial musculature, while adrenalin stimulates the sympathetic nerve fibres in the bronchi causing shrinking of the bronchial mucosa through vasoconstriction of the arterioles, at the same time producing bronchial dilatation through relaxation of the bronchial muscles.

Aminophyllin given orally has not proved very effective in relieving asthmatic attacks. It has sometimes been given intramuscularly with satisfactory results in 0.48 gm. (7½ gr.) doses which are furnished in 2 c.c. ampules.

It is sometimes effective in rectal injections, 0.48 gm. (7½ gr.) being administered in 20 c.c. of distilled water as a retention enema, or it may be given in a suppository containing 0.36 gm. (5½ gr.).

Since intravenous injections cannot be administered by the patient himself or very frequently at home by his physician, the patient requiring aminophyllin should ordinarily be hospitalized.

Aminophyllin finds its greatest field of usefulness in patients who temporarily are not relieved by adrenalin, and according to the Council of Pharmacy and Chemistry the American Medical Association[3] it is probably a safer drug than adrenalin in the occasional cases where there may be indecision regarding the "bronchial" or "cardiac" nature of the attacks. Intramuscular and rectal administration should be used more frequently than they have been.

Oxygen.—Oxygen, or oxygen with helium, is frequently administered to relieve distress from asthmatic seizures. In some cases immediate relief is secured.

Forty per cent oxygen at the rate of 4 to 6 litres a minute is the usual prescription. Continous oxygen is occasionally required, or seems to be, for considerable periods, as already mentioned. A mixture of helium and oxygen in the proportion of 80 per cent helium and 20 per cent oxygen offers the advantage that, inasmuch as the mixture has only about one-third of the weight of air, it is breathed more easily. Following the use of oxygen, patients who have become refactory to adrenalin may again be able to get relief from it.

Two ounces of ether with four ounces of olive oil per rectum is effective in securing relaxation for some patients. Occasionally general anesthesia has been employed with benefit.

X-Ray Therapy.—Schilling[10] in 1906 noticed that an asthmatic patient felt better after fluoroscopy, and various observers have since recorded improvement after x-ray treatment. Desjardins[5] has explained the benefit as due to the action of the x-rays in producing a decrease in the secretory power of mucous glands, a liberation of antibodies by the destruction of leukocytes and a stimulation in the production of eosinophiles.

However, although forty years have passed since Schilling's report, x-ray treatments have not yet been proven of extraordinary value for relieving or preventing asthmatic attacks. Whatever beneficial effect they may have does not seem to be lasting.

Enough has been said to indicate that the hospital treatment of bronchial asthma has usually meant rather desperate attempts on the part of the attending physician to meet an emergency to relieve a patient in dire distress, to treat a symptom without getting rid of its cause.

Morphine.—The administration of morphine is mentioned only to be condemned. Although the patient gets relief, sudden death is not uncommon following its administration. It is especially dangerous when used as a last resort. It probably causes death by depressing the cough reflex and the respiratory center. When it does not cause death directly, its use is likely to be followed by nausea and vomiting which definitely increase the mortality. Some allergic individuals, moreover, are hypersensitive to morphine itself, and frequently it causes pruritis, if no more serious result. It is not denied that in some cases morphine relieves when other measures have failed, but too often it quiets the patient permanently. Unger[11] reports five fatalities following the use of morphine to control asthmatic seizures, in 1926, 1928 and 1929.

Since abandoning its employment, only two deaths from asthma have occurred in his practice. As a matter of fact, except when morphine is used, deaths rarely occur during asthmatic seizures or in status asthmaticus. Often the patient wishes he could die but doesn't.

More than 10 per cent of the asthmatic patients at St. Mary's Hospital in 1944 and 1945 received morphine. Fortunately there was only one death in this series and that was not following its use.

Demerol, an opium derivative, in spite of Paul de Kruif's recent panegyric in the *Reader's Digest*[4] over its use in asthma, as God's own medicine, has not been found very useful or very safe.

Various other sedatives and hynotics are often helpful. Phenobarbital, seconal, amytal, or nembutal may be tried, but they may do harm if pushed to the point where the patient's ability to expectorate is lessened. One must be on guard for idiosyncrasies.

Most asthmatics endure necessary surgical operations fairly well. It is easier and safer to operate between the attacks, but when delay would be dangerous, it has often been found that the anesthesia brings on relaxation and long-continued relief. Morphine should not be given in the preparation of the patient. Substitutes such as the barbiturates (nembutal, amytal, and phenobarbital) should be employed instead. Aspirin should not be given, unless it has been ascertained that the patient is not hypersensitive. One of our patients had a nearly fatal shock after being given 5 grains. Still it was not infrequently ordered in the series.

Febrile diseases are not especially influenced by the presence of asthma, and during their course the patient may have temporary relief from his attacks. This was true in one of our cases, an old lady, who, while having frequent asthmatic seizures, developed bronchopneumonia for which she was hospitalized. During its course she was free from asthma, but it recurred following her convalescence. Did her fever act as a form of therapy? On the other hand, head colds and sore throats often precipitate asthmatic attacks.

Specific Treatment.—Separation of the patient from exposure to the allergen for which he has acquired a greater or less degree of sensitivity is a form of specific treatment. Sometimes the offending substance is already known to the patient; hence, the value of careful history taking. Removal of the patient from his home to the hospital may shed light on the subject. If the attacks cease, the allergen may be absent in the new environment.

If not known or discoverable in this way, valuable leads may be given by careful skin testing, though often enough some of the substances to which the patient responds by positive reactions are not the one which produce his symptoms. He may react positively to substances with which he rarely comes in contact, or of which he encounters such small amounts that this threshold of sufficient susceptibility to permit an attack is not reached. His sensitivity to some other substance may be the one that really causes the trouble.

Satisfactory skin testing requires skill and experience and judgment. The tests may be on the patient's skin, or if for any reason, such as the presence of skin eruptions or a general condition of debility or depletion, this is not practicable, they may be done on the skin or another person who, however, must not be an allergic individual himself. This indirect form of testing is based on the Prausnitz-Kustner[10] phenomenon, in accordance with which the patient's sensitivities can be transferred to a limited area of the skin of another individual by preliminary injections into it of the patient's serum.

Whether the direct or indirect methods of testing are chosen, care must be used to avoid overdosage, as severe constitutional reactions and even fatalities have resulted in some cases. The patient who is being tested should remain in the physician's office long enough for untoward symptoms to develop, and restoratives should always be at hand in case syncope occurs.

The tests are performed in various ways—on the skin by simple contact or patch methods, and in the skin by the scratch or by intracutaneous procedures. They are time consuming and should be directed and observed by one thoroughly familiar with them, preferably a trained allergist.

When the substance or substances to which the patient is sensitive and which appear to be responsible for his asthmatic attacks are identified, breaking of contact with them is sometimes quite simple. Food allergens may be omitted from the diet. The face powder may be changed if it is responsible. Contact with animal dander may cease when the dog or cat is banished. Offending pollens may be avoided by moving to a place where they do not exist, or are not sufficiently abundant to overcome the patient's modicum of resistance, as in the hay fever havens of America where the breezes blow them away. If one must stay where there are pollens to which he is supersensitive, air filters and air conditioning may help to keep them out of a room.

If considerable contact is unavoidable, desensitization may be tried. Perhaps hyposensitization is a better term since complete and permanent desensitization is rarely possible. The best that can usually be hoped for is a reduction of the patient's sensitivity.

This form of treatment may be given orally in case the allergens which distress the patient are foods. If they are pollens or bacteria, a series of hypodermic injections of extracts or suspensions is used.

Dosages, solutions and time intervals differ somewhat in various hands. The principle is the same that underlies immunization to tuberculin by Dr. Trudeau's method. Very minute doses are given at first. The dose is gradually increased. Every effort is made to avoid general reactions. It is remarkable with what high dilutions they may occur even after the use of what seems like homeopathic attenuations of the dosage.

Fatal shock has occurred more than once during specific treatment, and, though infrequent, the possibility of its developing should be kept in mind and guarded against.

The exact technique, the dosage and spacing of injections, the best and latest methods of preparing and administering extracts are described in current literature on allergy and should be followed to avoid disaster.

Very satisfactory results have been obtained from hyposensitization treatment by experts.

Unger[11] secured freedom from symptoms for at least a year in this way in 33.6 per cent of 122 patients whose asthma was due to pollen.

The best results come from perennial rather than merely seasonal or preseasonal treatments.

Asthma has been classified by some authorities as *extrinsic*, due to substances from without the patient's body to which he has become sensitized and which reach his trigger cells in the bronchial mucous membrane by inhalation or the blood stream, and *intrinsic*, due to substances already present within the body. Upper respiratory infections frequently initiate asthmatic attacks, and at times no extraneous allergens can be found that are responsible. A patient may originally have become asthmatic as a result of sensitization to external antigens and may have been desensitized, but in the meantime have developed bacterial sensitivity which continues his asthma. In some such cases desensitization with bacterial vaccines has been helpful. Autogenous vaccines are to be preferred, but stock vaccine may be used.

Since a histamine-like substance is believed to have an important part in producing the allergic paroxysms, as well as in other forms of shock, efforts have been made to desensitize the patient to histamine. Histamine and histaminase have been used in Duluth as elswehere for this purpose. Recently, Horton and his co-workers[7] in the Mayo Clinic have been experimenting along this line with a new preparation known as benadryl, which has been given some publicity. It has been tried with encouraging results in other allergic conditions such as hay fever and eczema, but no remarkable success has yet been noted with asthmatic cases. Histamine is so intimately concerned in various bodily functions that the question may be raised whether complete desensitization to it would be desirable. Insulin and fever therapy have also been used in the treatment of asthma.

It is not to be expected that any form of treatment that merely relieves an attack of asthma is going to prevent recurrences. Lowering the patient's threshold of sensitivity by specific treatment is of more value, but even this will not suffice to keep the patient comfortable without avoidance of conditions which cause depletion and debility.

Nothing can be done to remove entirely the congenital handicap, the inherited constitution. With such an inheritance, the development of some degree of hypersensitivity to various allergins is inevitable. The physician's problem is the prevention of the more serious degrees of allergic response. If the child is already developing eczema, every effort should be made to forestall hay fever and especially asthma. Allergic children are a special responsibility. Allergic families must be recognized and their future health guarded. If the reactions can be kept minimal, they may not cause too great a handicap, but if these cases are neglected the results may be dire indeed.

The distress suffered by patients who have severe bronchial asthma is pitiable and is probably as hard to bear as the pains caused by cancer or heart disease, with the added foreboding of many future attacks. More appreciation of the courage and heroism of those who endure them should be shown. The sequels of repeated attacks may be definite pathological conditions of various kinds. Emphysema commonly results from them and eventually heart strain. Various conditions, migraine, gastrointestinal crises, Meniere's disease and the dreaded periarteritis nodosa have all been suspected of allergic affiliations.

The child born with an allergic tendency, a capacity for becoming hypersenitive to all sorts of allergens, should be guarded from exposure to excessive amounts of the more common and notorious ones. If a certain amount of contact with them is unavoidable, his general health and resistance must be kept at a high level throughout his whole life. This is a large contract. The men who have suceeded best in fulfilling it have not merely been skilled allergists, but they have approached the problem with the broad view of experienced internists, and in addition to specific measures have used a considerable amount of psychosomatic therapy. The patient's morale must be kept up. His apprehensions must be relieved and freedom from fear secured if possible. He must have a strong arm to lean on. His handicap may, to a large extent, often be overcome.

There are a number of men in the larger cities who in this way have made life worth living for a large number of patients during a series of years. Such help is needed everywhere.

So far we have not considered bronchial asthma as a social problem. The actual number of asthma cases is unknown. The condition is not reportable. Five-tenths of one per cent of selectees for military service in a group of 45,000 were rejected because of severe allergic states, chiefly asthma,[6] and it may be assumed that that percentage approximately represents its prevalence. There are probably several hundred thousand asthmatic persons in the United States, of whom a considerable proportion are wage earners. As already stated, perhaps 10 per cent of the population show some evidence of allergic predisposition. The avoidable economic loss from impaired working capacity is certainly worth salvaging. The expense to welfare agencies from asthmatics seeking hospital relief and change of climate is very considerable.

A national crusade for the prevention and control of asthma has been advocated and doubtless will materialize. It should follow the lines already laid down in other successful health promotion efforts. They represent the combined efforts of the medical profession and the lay public. Research should be a necessary part of the program. The facts about the condition should be widely publicized.

The services of experts in treatment should be made available to all patients. As regards asthma, physicians should recognize the occurrence of allergic families and discourage intermarriage. The children of allergic patients should be treated as

NITROGEN BALANCE AND ITS CLINICAL APPLICATION

ROBERT E. HANSEN, B.S., M.D., and EDWARD L. TUOHY, M.D., F.A.C.P.
Duluth, Minnesota

THE term nitrogen balance connotes the degree of equilibrium of the body in terms of nitrogen taken into the organism and the amount lost. The main routes of nitrogen loss are through the urine, feces and exudates. In cases where the organism sustains an illness or injury, some of the body tissues are catabolized, the nitrogen excretion exceeds the ingestion of nitrogen, and the body is said to be in negative nitrogen balance. As recovery progresses the body retains more nitrogen than it excretes, thereby acquiring a positive nitrogen balance.

Since nitrogen is one of the important substances in protein, and because it is the element with which we can deal objectively in studies to determine the protein status of our patients, we will frequently use these terms, nitrogen and protein, interchangeably in this discussion. An important decisive fact to remember is that quantitatively 1 gm. of nitrogen is equivalent to 6.25 gm. of protein, or protein contains 16 per cent nitrogen.

During the past several years, the interest in protein metabolism has increased considerably. Undoubtedly the past war has exerted a great influence in this direction. One of the authors (R. E. H.) has observed the mark of protein deficiency in many European people. It was dramatic, it was pitiful, and it was deadly. We must diligently remember that protein deficiency is not a rare phenomena which is confined to the unfortunate, malnourished and starving peoples. Even those who have been blessed with health, wealth and an abundance of excellent food may feel the sting of protein deficiency should they suffer from a fracture or convalesce from an operation or illness. And let us not forget the women in gestation who require careful protein consideration, because the human embryo will most certainly demand its "pound of flesh."

Hemostasis names the physiologic process of normal balance and adaptation. We propose to emphasize the protein factor therein.

Nutritionally, the proteins are assuming the principal role for which they got their name from the Greek—first in body rebuilding. One might say that we as humans are essentially suspensions of proteins in water.

Students of protein metabolism have advanced several theories in an attempt to explain this body function. More recently Borsook and Keighly[3] have emphasized the factor of dynamic equilibrium in which breakdown and resynthesis proceed hand in hand—dietary nitrogen replacing tissue nitrogen, and the nitrogen of various organs undergoing continuous interchange. Even in a starving animal, tissue protein does not undergo catabolism alone, but is being continuously resynthesized, new protein being formed in one tissue from nitrogen derived from another.

Chemically, proteins are organic molecules composed of linked amino acids. Nutritionally, proteins are considered to be of two types, the superior and inferior—the superior being the protein with a high biological value and adequate digestibility. Animal proteins are classed here. They have a high biological value because they contain the essential amino acids (ten in all) in the proportions which closely resemble human protein. They have a 95 to 100 per cent digestibility. The inferior protein is one which is lacking in one or more of the essential amino acids or which is less digestible and absorbable. The vegetable proteins tend to fall into this group. The ingestion of inferior proteins alone necessitates wastage of its end products. The amino acids of the protein are broken down and excreted instead of entering into tissue protein, and, as a result of this, body tissues have to be broken down to furnish essential amino acids for protein metabolism. In such a situation the body enters into a negative nitrogen balance. Now how does all of this fit into a person's average daily existence? It is definitely true that a person on a well-balanced mixed diet will get all the essential nutrients. It is only when the protein intake is restricted or unutilized that one must give exact consideration and choose proteins of high biological value.

The process of protein digestion is relatively simple—the molecules are acted upon by enzymes in the stomach and small intestine, breaking them into proteoses, polypeptides and amino acids. The

---

From the Department of Medicine, St. Mary's Hospital, Duluth, Minnesota.

amino acids and polypeptides are absorbed and enter the portal circulation and lymph, and then the general circulation. We can readily see that any disturbance in the normal digestion of protein will definitely affect the ultimate protein metabolism, chiefly by reducing the amount of amino acids absorbed. The stool nitrogen in such cases will increase, and this is the basis of the generally utilized methods of studying nitrogen balance.

When the amino acids attain the circulation, they are either used for the restoration of tissue, for the building of hemoglobin or plasma proteins, for the manufacture of hormones or intestinal enzymes, or they are sent to the liver and deaminized, releasing carbohydrate for energy and diverting nitrogenous elements for urinary excretion.

Let us consider the production and maintenance of tissue protein, plasma protein and hemoglobin. The body gives first consideration to the production of hemoglobin, which takes preference over other body protein needs. It may draw from the tissue and plasma proteins, but does not in turn contribute to the protein pool. Perhaps this is the explanation for the rare occurrence of a true protein deficient hypochromic anemia in this country. Usually we see the iron deficiency type. Considering now the tissue protein, we know that every tissue must retain a minimum level of protein if it is to live. Under normal circumstances, cells contain more than the absolute minimum, and some of these proteins are in a labile form, readily available to the body if needed. This protein has been termed the "deposit protein." In a well-nourished, average-sized man this measures about 2 kg., which actually is a small amount. In addition to the hemoglobin and tissue protein there are the plasma proteins, which have three constituents: (1) fibrinogen, formed chiefly in the liver and used in the clotting mechanism, being converted by thrombin into insoluble fibrin; (2) globulins (alpha, beta and gamma) which are intimately concerned with certain pathological functions, such as antibody formation, and are formed in the liver and lymph nodes, and (3) albumin which is formed in the liver and is responsible for the maintenance of the osmotic pressure of the blood. It is this serum albumin which is lost in the urine in nephrosis; it is the predominant protein lost in exudates; it is the protein primarily affected in hypoproteinemia.

Because a dynamic equilibrium exists between the plasma and tissue proteins, a lowering of the serum albumin occurs only after the body proteins have been severely depleted. Elman[8] has shown that a loss of 1 gm. in the total circulating serum albumin entails the destruction of 30 gm. of body protein. For example, an average-sized man (70 kg.) has a circulating volume of 3 liters. If he loses 1 gm. of albumin per 100 c.c., it corresponds to the loss of 10 pounds of flesh. Return of the plasma albumin concentration to normal may occur before, and often long before, the body deficit is made up, but is probably only temporary and a prompt fall would result unless the protein intake is maintained. Thus the return to a normal plasma albumin indicates that the treatment is effective but not necessarily complete, and that the high protein food intake must be maintained until normal weight and strength are regained. At Halloran General Hospital, Sprintz[15] observed that a group of soldiers with chronic infections who lost one-third to one-half their original body weight following injury showed no hypoproteinemia or abnormal albumin-globulin ratio. In the presence of normal plasma proteins there may be a marked depletion of body tissue. Only if there is a low plasma protein can one attempt to make an accurate statement regarding the state of the tissue protein.

The diagnosis of protein deficiency depends upon the clinical symptoms and signs, corroborated by laboratory studies. The clinical picture is familiar to us, manifested by anorexia, weakness, mental depression, failing memory, weight loss and edema. The edema level is recognized as about 5 gm. per cent. The laboratory procedures which objectively assist in the diagnosis are: the hemoglobin determination, the plasma protein analysis and the nitrogen balance studies. The Kjeldahl procedure or one of its modifications may be used for the study of nitrogen elimination. In addition, measurements of strength and endurance by a physical fitness test or an ergograph[4] have proved to be valuable assets. The study of weight curves has been a convenient method to aid in the evaluation of a patient's protein status. Wangensteen and Varco[18] advocate the feeding of a high-protein, high-caloric diet to surgical patients who have lost body weight. They recommend at least a week of nutritional preparation for every 10 per cent of the original body weight lost. Perhaps the disadvantage of weight studies is the possibility of large fluid shifts which may mask the loss or gain of flesh.

Let us consider here two factors which affect protein metabolism—the energy requirements of the body and the special demands made during injury or illness.

The energy requirements are of paramount importance to the body and are supplied first. The three necessary nutrients are carbohydrate, fat and protein, which furnish energy at the rate of 4, 9, and 4 calories per gram, respectively. The body uses about 1,800 calories, and if this energy is not supplied in the diet, the body burns its own stores. If the body cannot obtain sufficient calories from the fat and carbohydrate, the protein catabolism is greatly increased and one can observe the "terminal rise" of nitrogen excretion, so named because the organism would die shortly after its appearance. This process is known as auto-cannibalism. Carbohydrate exerts a specific protein sparing effect apart from the fact that it furnishes energy as does fat, because the sparing effect exhibited by a given amount of carbohydrate cannot be brought about by the same amount of fat possessing double the caloric value.[2] Carbohydrate alone has a marked sparing effect, whereas fat alone does not, a positive nitrogen balance cannot be maintained on a diet of protein and fat. A probable explanation for the great sparing effect of carbohydrate is that its intermediary products of metabolism make it possible for the nitrogen resulting from tissue breakdown, in a predominantly protein and fat diet, to be used in resynthesizing amino acids for body protein.

The demands upon protein metabolism during injury or illness have added new interest and stimulus to a consideration of what happens thereto after injuries, operations or physiological upsets which occur in infectious processes, chronic wasting, malignant disease and metabolic disturbances. A review of some of the recent reports features certain dramatic and unsuspected breaks in nitrogen metabolism.

Following extensive burns, a hypoproteinemia is known to occur, due to several factors such as tissue destruction, loss of serum protein in exudates, failure of hepatic function in protein synthesis and loss of ingested food because of diarrhea or vomiting. The extent of protein loss in exudates has been shown by Co Tui[5] to vary from 1.2 gm. to 9.5 gm. per day. The extent of urinary nitrogen loss after severe burns was demonstrated by Taylor,[16] who found, in a series of twenty-two cases, a nitrogen loss of up to 45 gm. in one day, which is equivalent to about 280 gm. of protein.

The resutls of a study conducted by Hirshfield and associates[11] on twenty-three cases of thermal burns, revealed that patients excreted rather large amounts of nitrogen, and unless they were receiving a high-caloric, high-nitrogen intake, they showed a negative nitrogen balance and weight loss. Attempts were made to force large amounts of food in the early acute stage but proved unsuccessful because of intolerance. However, after three or four days the patients were able to take abundant food, and the body response showed a definite swing to a positive nitrogen balance. During the initial acute phase when the patients were unable to tolerate large diets, they were given intravenous protein hydrolysates. At present most authors agree that the use of parenteral hydrolysates should only be used during emergencies, and replacement by oral therapy at the earliest moment is greatly advantageous.

Protein deficiency develops frequently and insidiously in patients anticipating operation for peptic ulcer or gastrointestinal malignancy. In contrast, Thorton[17] did not find this commonly in patients requiring thoracic surgery. Hartzell[10] reported it in general surgical patients and Bartels[1] noted its significance in patients needing thyroidectomy. Postoperatively, the average surgical patient lapses into negative nitrogen balance unless attention is paid to the adequate intake of protein. Co Tui[6] and his associates studied nitrogen metabolism in eight patients following gastrectomy. Four patients received the usual postoperative standard ward diet of weak tea followed by frequent small feedings, slowly increased; the other four patients received large amounts of protein in the form of casein hydrolysates, which were given by a gastric tube. The results were remarkable. Those fed on the usual ward routine were in negative nitrogen balance, lost weight, regained their strength slowly and had a protracted convalescence. In contrast, the patients receiving protein hydrolysates were in positive nitrogen balance, gained weight, regained strength rapidly and had a shortened convalescence.

Others have studied the same problem in various surgical procedures such as herniorrhaphy, appendectomy and cholecystectomy. They have found that patients who are fed a high-caloric diet and are given high-protein materials parenterally and orally remain in a positive nitrogen balance and gain weight and strength in about one-half the time of those in negative nitrogen balance because of inadequate protein intake.

Some interesting work has been done at the Johns Hopkins Hospital[12,13] on nitrogen studies in patients with fractures and in those who had osteotomies. A series of six cases of fractures of the large bones of the lower extremities in otherwise healthy males revealed that these patients reached their maximum negative nitrogen excretion on the sixth postfracture day; their total nitrogen loss amounted to about 200 gm. This expressed in terms of protein would be 1,400 gm.; in terms of body tissue it equals 15 pounds. The duration of the negative nitrogen phase lasted thirty-six days. Some of these patients were studied for an additional three weeks, and it was found that they replenished their lost nitrogen at a slow rate—only 15 per cent replacement over a three-week period on a diet of 120 gm. of protein in 2,600 calories. In the cases of osteotomies these patients reached their maximum negative nitrogen excretion on the fourth day; their total nitrogen imbalance lasted nine days. Their nitrogen was restored rapidly by comparison—75 to 90 per cent in three weeks.

In the field of radiology some studies have been made at Harvard[9] which have described the nitrogen metabolism changes after use of deep x-ray therapy. In general, it was found that a shift toward a negative nitrogen balance occurred during irradiation, followed by a return to a positive balance after treatments. The negative balance tended to be delayed about forty-eight hours after beginning treatment. There was a correlation found between the degree of nitrogen loss and the sensitivity of the patient's lesion to x-ray. The patients with the most sensitive lesions would excrete the greatest amount of nitrogen, and there did not appear to be any correlation between the nitrogen loss and the dosage of x-ray. The basis for the negative nitrogen balance was the amount of tissue destroyed.

The problem of nitrogen balance occupies a prominent phase in the medical field. Of the metabolic diseases, thyrotoxicosis, Addison's disease, and diabetes mellitus present a special problem in protein metabolism. Patients who exhibit thyrotoxicosis have a greater protein need because of the increased metabolism. Weight loss may be extreme and the muscle and liver protein may be greatly reduced. A high-caloric, high-protein diet is indicated in conjunction with specific measures of treatment. It is well established in untreated or poorly controlled diabetes, that large quantities of nitrogen are excreted in the urine as the result of increased conversion of protein to carbohydrates. As a consequence of this, a large protein deficit may occur. Insulin will correct this, but an ample amount of protein is needed to correct any existing deficiencies. Great weight loss occurs in Addison's disease. Regardless of the complexities involved, it is evident that "protein sparing" by carbohydrate and fat is defeated.

In liver disease a positive nitrogen balance is a must. Cirrhosis produces liver impairment and interference with gastrointestinal function. The liver impairment is the cause of plasma protein imbalance because the liver is unable to synthesize the albumin properly. The mechanism is unknown, but clinically we know the difficulty in maintaining the serum albumin in patients with advanced cirrhoses. A study of five cases of cirrhosis by Post and Patek[14] revealed that though the patients were given high-protein diets, the serum albumin showed no correlated rise with the protein feedings. This is in direct contrast to the results obtained in cases of protein starvation without primary liver disease where the serum albumin does reflect the protein intake. This study on patients with liver cirrhosis showed that the absorption of protein was adequate (the fecal nitrogen was normal) and that the retention of nitrogen was definite as shown by the positive urinary nitrogen balance. The possible explanation for the failure of the serum albumin to increase is the faulty synthesis of the albumin by the damaged liver. In cases of infectious hepatitis the early prescribed treatment was that of a high-carbohydrate, high-caloric diet, the purpose being to restore liver glycogen and limit hepatic damage. All recent studies emphasize the greater value of protein in protecting the liver cells, especially the amino acids, cystine and methionine, which contain sulfur.

Such illnesses as chronic peptic ulcer, chronic pancreatitis, regional enteritis, ulcerative colitis, chronic gastritis and gastrointestinal malignancy have a marked effect upon protein balance and they do so because of anorexia, restricted diets, vomiting, intestinal hypermotility with diarrhea, draining fistulas and excessive putrefaction. The resultant negative nitrogen balance with hypoalbuminemia and edema of the bowel aggravate the already present gastrointestinal dysfunction, producing a vicious cycle. Because these diseases are likely to be chronic and exhibit some permanent structural or functional change, the vital factor is the proper maintenance or a satisfactory daily diet over a long period of time. However, such measures as repeated feedings of small quantities of highly nutritious food, supplemented by oral or parenteral amino acids and the use of blood transfusions, may be needed at times to correct acute deficiencies.

The role of protein in infection is still undergoing much investigation. As concerns the infection itself, perhaps there occurs a failure of antibody response in hypoproteinemic patients, because we know many of the circulating antibodies are found in globulin fractions. With regard to convalescence it has been shown that patients who have survived the acute infection will recover more rapidly and completely if they have an adequate protein and caloric diet.

We have stressed the close relationship of nitrogen balance or protein metabolism to various surgical and medical conditions, and we have shown that it is necessary in the proper treatment of many illnesses of man. Now, how can we supply the necessary proteins and keep a positive nitrogen balance in our patients? *The most effective and satisfying way is good, properly chosen food by mouth.* Unfortunately there is a limit to the amount of food a sick person can take, or will eat, and the problem of hyperalimentation can only be solved by the use of supplementary feedings. However, the use of parenteral feeding should be dictated by necessity and not by convenience.[7] In the acute cases, where hypoproteinemia is caused by surgical shock, burns or hemorrhage, the best protein replacement is plasma and whole blood; however, in chronic cases this is not too effective and is very expensive. For example, to give 100 gm. of protein by plasma or blood one would have to give the equivalent of six pints of whole blood; the hemoglobin is worthless as far as aiding tissue construction even though there is a good quantity present. For the chronic cases needing protein, there are the protein hydrolysates which are mixtures of amino acids prepared by either acid hydrolysis (splitting) or enzymatic hydrolysis. These preparations are not as expensive as whole blood or plasma and may be used in large quantities either parenterally or orally. Complete parenteral feeding can be accomplished with the amino acids, glucose, minerals and vitamins, and can be continued for one or two weeks. However, this will rarely be necessary and the early use of oral administration is strongly advised. A disadvantage of the oral route is that most hydrolysates have an unpleasant taste, and one must search for a suitable disguising vehicle. When hydrolysates are used, one must not forget that it is necessary to add vitamins, minerals, glucose and fatty acids to the diet so that the nutritional support is complete.

In conclusion, there is in the current medical literature much on experimental and clinical investigation upholding the present-day concept of protein as the most important dietary constituent in health and disease. It justly deserves to be called the "magic of life." The problem of nitrogen balance touches everyone who is confined to bed for some injury, operation, or illness. It even has become a problem for study in perfectly healthy individuals who were put to bed for a period of five days, because they, too, showed a negative nitrogen balance.

For routine medical practice, checking of nitrogenous equilibrium by complicated estimates of nitrogenous loss (urine and feces) is impractical. As we have implied, however, a knowledge of the situations where nitrogenous wastage is known to occur puts the clinician on his guard. It is easy to get laboratory estimates of blood and other tissue fluids, yet gross estimates are more informative. We may easily chart the weight curve and know that the period required for protein restoration takes more and more time dependent upon the degree of nitrogen deprivation; and the law of receding returns is dictated by the circumstance that the bodily machine (like a factory) must first build its component parts before it functions as a whole. Streamline mass production (no effort lost) is demonstrated only with the factory clicking in full co-operation—supply and disposal—a healthy unit. So it is with human economy.

OBSERVATIONS ON THE MANAGEMENT OF VASOMOTOR RHINITIS*

JAMES B. McBEAN, M.D.
Rochester, Minnesota

MOST rhinilogists would agree that vasomotor rhinitis is one of the unsolved problems in the specialty. Many excellent articles on the subject have appeared in the literature of recent years, but the multiplicity of treatments suggested and the variation in results obtained from them lead to the conclusion that the etiology, pathology and physiology of this condition are not well understood.

In order to limit this discussion, seasonal hay fever or pollen allergy will not be included in the term "vasomotor rhinitis."

Allergy and Anaphylaxis

It is commonly recognized that scratch tests or intracutaneous tests do not always produce positive results among patients who have perennial vasomotor rhinitis. Hansel[10] said that results of skin tests are reliable in the presence of pollen allergy, but that when other types of allergy to inhalants or food occur, skin tests may not be of value. We are all familiar with the patient who has vasomotor rhinitis but whose particular allergen cannot be detected even after a history has been carefully taken and skin tests and an elimination diet have been employed. Urbach suggested that in cases in which an allergen can be identified the condition should be termed "allergic rhinopathy," and that when no extrinsic allergen can be demonstrated the condition should be called "pathergic rhinopathy." He used the word "rhinopathy" rather than "rhinitis" because, pathologically, the condition in question is not characterized by inflammation. Williams[26] distinguished between the antigen-antibody type of allergy and the intrinsic or physical form of allergy. Hay fever is an example of the former, and nonspecific vasomotor rhinitis is an instance of the latter. Williams devised the term "syndrome of intrinsic allergy," which includes vasomotor rhinitis, Ménière's syndrome, myalgia and the vasodilating pain syndrome. He gave numerous references to support the theory that the allergic reaction, whether antigen-antibody or intrinsic, is accompanied by damage to cells as histamine is released into the tissue spaces. This reaction may be produced by a specific allergen or antibody or by various other factors which are nonallergic in nature. The latter include cold, heat, changes in atmospheric pressure, emotional disturbances and endocrine dysfunctions. Other authors have supported the view that in many cases vasomotor rhinitis is nonallergic in origin; among such authorities are Paterson, who wrote that vasomotor rhinitis is a localized manifestation, in the nasal mucous membrane, of generalized nervous imbalance, and Laub, who believed that vasomotor rhinitis is caused by imbalance in endocrine secretion.

Although anaphylactic shock in the experimental laboratory and allergy in the human being are not identical, there is a close similarity between the two reactions. Code[1] has said that the formation of a toxic chemical substance during anaphylactic shock was one of the first mechanisms suggested for the production of the symptoms of that reaction. He quoted Dale and Laidlaw (1910), who pointed out the similarity between the phenomenon of anaphylactic shock and the physiologic action of histamine. Code raised the question of whether histamine is present in the blood plasma or is held within the cells. In some very interesting experiments he found that in the blood of dogs and rabbits 74 to 89 per cent of the total histamine content of the blood was present in the leukocyte layer of centrifuged blood. In the same paper he reported that during anaphylactic shock in guinea pigs the total content of histamine in the blood was three to nine times the normal value. He also found that the usual ratio of histamine-to-plasma and histamine-to-leukocytes is reversed, meaning that during anaphylactic shock the major portion of the histamine is in the plasma, whereas the histamine content of the leukocyte almost disappears. Code emphasized, however, that the release of histamine into the blood plasma does not account for the whole picture of anaphylactic shock, for example, the incoagulability of the blood and the fact that dogs sometimes die some hours after anaphylaxis has been induced and after the histamine content of the blood has returned to normal. He suggested that histamine is released as a consequence of damage occurring within the sensitized cells, and that it is the damage to such cells that is the fundamental etiologic factor in the allergic or anaphylactic reaction. Dragstedt has raised the question of whether this substance is histamine or a "histamine-like substance."

*Read at the meeting of the Milwaukee Oto-Ophthalmic Society at Milwaukee, Wisconsin, January 28, 1947.

From the Section on Otolaryngology and Rhinology, Mayo Clinic, Rochester, Minnesota.

Troescher-Elam, Ancona and Kerr reported finding a histamine-like substance in the nasal secretions of both patients who had allergic rhinitis and patients who had the common cold. They found that the amount of this substance varied widely in the two conditions, and also found no correlation between the amount of the histamine-like substance and the number of eosinophils in the secretion.

Clinical Observations

The diagnosis of vasomotor rhinitis can be made on the basis of paroxysmal attacks of sneezing, with nasal congestion and watery or mucoid discharge. The mucosa of the nose usually appears pale and waterlogged, and a mucoid discharge is present. If the disease has not progressed too far, and is in a period of remission, the nose may appear normal on examination. The presence of polyps indicates long-standing disease. If a purulent discharge also is present, it indicates the presence of secondary hyperplastic sinusitis.

Hansel,[9] in his comprehensive monograph, referred to numerous sources regarding the significance of eosinophils in the nasal secretions of patients who have nasal allergy. More recently, Hald, D. Miller, and A. R. Miller reported on the significance of cytologic examination of nasal smears. It seems to be a well-substantiated fact that eosinophilia of the nasal secretion indicates the presence of allergy. At the Mayo Clinic, cytologic examination of nasal smears is not carried out routinely, because it is believed that a diagnosis can be made, in most cases, without it.

It is worthwhile for the physician to spend some time in questioning the patient about the relationship of his nasal symptoms to environmental factors, such as animals, house dust, occupational dusts and fumes, foods and drugs, as well as such nonallergic factors as cold, heat, changes in weather, fatigue and nervous tension. Because results of cutaneous tests are not always reliable in vasomotor rhinitis, the type of history mentioned in the preceding sentence frequently will be of more help than such tests. This is in contradistinction to the situation in seasonal hay fever, in which results of skin tests are much more reliable.

When the history indicates that the patient has extrinsic allergy, cutaneous tests should be carried out. At this point I should like to urge that the rhinologist himself perform cutaneous tests for patients whose allergic symptoms are confined to the nose. The great majority of these patients will consult a rhinologist first; he may save the patient much time and expense if he himself will do the relatively few tests needed.

Treatment

In our experience at the clinic, desensitization of a patient to the usual specific allergens which cause perennial vasomotor rhinitis has not been very successful. It is rather a question of avoidance of the offending substance. Elimination of animal pets in the home, avoidance of certain foods or drugs, and possible change of occupation all should be considered.

Hansel[9-11] and Shambaugh wrote that house dust is a major factor in most cases of vasomotor rhinitis. Shambaugh said that underlying nasal allergy is responsible for chronicity in at least 70 per cent of all cases of chronic sinusitis and 90 per cent of all cases of chronic rhinitis. He also wrote that if pollinosis is excluded, house dust is a major factor in at least 90 per cent of all cases of chronic nasal allergy. As a corollary to this theory, Shambaugh and Hansel recommended desensitization with house dust in cases in which results of cutaneous tests are negative. They stressed the use of very small initial doses and of gradual increase in such doses, until the optimal symptomatic relief is obtained. At such a time an adequate maintenance dose is to be employed. No definite rules for dosage can be given, because the condition of every patient is an individual problem. Hansel believed that many therapeutic failures, when desensitization with house dust is employed, are caused by the fact that treatment was begun with too large a dose, or that the dose used was increased beyond the optimal point.

There are several nonspecific measures that should be carried out, and these will give relief to many patients. Houser, in a recent article, discussed these empiric measures; they include the use of dustproof covers on pillows and mattresses, hypo-allergic cosmetics, elimination of household pets and cessation of the use of nose drops and inhalers.

Williams[28] has said that the overuse of nose drops is responsible for many instances of chronic nasal congestion. Lake applied the term "rhinitis medicamentosa" to such instances. At the Mayo Clinic many of our patients who have vasomotor rhinitis derive at least some improvement from cessation of all intranasal medication. Feinberg and Friedlaender have reported on chronic nasal congestion which is said to arise from the frequent use of a naphazoline nasal vasoconstrictor (privine hydrochloride).

Schall held that vasoconstrictors give only temporary relief; he advised against their use. He said that the basic pathologic feature is edema and dilation of the cavernous spaces. He recommended subepithelial electrocoagulation or destruction of the dilated spaces by means of the careful injection of sclerosing fluid. The agents recommended are a 5 per cent solution of sodium morrhuate or of a proprietary sclerosing agent (sylnasol).

Histamine and nicotinic acid.—The physiologic effects of histamine are known to be: (1) contraction of smooth muscle, (2) constriction of arterioles, (3) dilatation and increased permeability of the capillaries, with localized edema and (4) increased secretion by the secretory glands. This subject was discussed by McLaurin, as well as by Williams and Code, previously referred to herein. Because of the similarity between the action of histamine and the symptoms of allergy, these authors have treated vasomotor rhinitis by small doses of histamine in an attempt to desensitize the patient. McLaurin used histamine azoprotein, and reported eventual good results in the treatment of all but two of 102 patients. The two patients experienced recurrence. Farmer and Kaufman administered histamine subcutaneously to forty-one patients who had nasal allergy. The initial dose they used varied from 0.01 gamma (1/1,000 mg.) to 0.1 gamma. The highest dose they used was 100 gammas. They reported good results in twenty-five cases, fair results in ten, and poor results in six. Gant, Savignac and Hochwald administered dilute solutions of histamine by mouth, and attempted to provide immediate relief during attacks of vasomotor rhinitis. They reported on thirty-three patients, three of whom were un-co-operative. Of the remaining thirty, all but two were relieved by this treatment. The dose varied from 1 drop of a 1:1,000 solution to 25 drops of a 1:100 solution. The average dose was 5 to 7 drops of a 1:1,000 solution of histamine in a glass of water. Williams[26] treated his series of patients with twice-daily subcutaneous injections of histamine. In most of his cases he started with 0.1 c.c. of a 1:50,000 solution of histamine base and increased this by 0.1 c.c. each time, until symptoms disappeared or an objective return to normal was noted in the nose. The maintenance dose varied between 0.1 c.c. of a 1:50,000 dilution and 0.1 c.c. of 1:1,000 dilution of histamine base. He found, however, that in most cases in which relief was obtained, the symptoms recurred on cessation of treatment. He obtained good results for thirty-three patients and fair results for seven. For eighteen patients the treatment was a failure.

Harris and Moore first suggested the use of nicotinic acid in the treatment of Ménière's disease. They felt that the association of perceptive deafness with vertigo suggested the presence of a degenerative disease, and they further noted that a high percentage of pellagrose patients had vertigo. They administered thiamine chloride without benefit, but when 250 mg. of nicotinic acid was added daily, seventeen of twenty patients were relieved of vertigo. As stated previously, Williams said that vasomotor rhinitis and Ménière's disease are part of the intrinsic allergy syndrome. Consequently, he treated a series of patients with nicotinic acid with about the same results he had obtained from histamine.

At the Mayo Clinic nicotinic acid now is being administered to many patients who have vasomotor rhinitis. The dose must vary to some degree to fit the requirements of each patient, but the average patient receives subcutaneously an initial dose of 25 mg. of nicotinic acid (niacin), and this amount is increased by 25 mg. twice a day until 100 mg. is being administered twice daily. After a few days the patient is sent home to take 100 mg. once a day subcutaneously for one to three months. If symptomatic relief is obtained and if it continues, the patient may change to the oral form of administration and take 100 mg. of nicotinic acid twice a day. So far as is known now, this medication can be continued indefinitely, although in many cases it is possible to reduce the dose to 100 mg. taken two or three times a week.

It is too early for me to make any statement as to the long-range results of nicotinic acid therapy among my patients. I am able to say, however, that many of my patients who have vasomotor rhinitis are relieved of their symptoms over a period of several months.

Benadryl.—Beta dimethylaminoethyl benzhydryl ether hydrochloride (benadryl) is a synthetic substance which has the property of counteracting many of the physiologic effects of histamine. If the theory that the type of allergy under consideration is due to the release of histamine is true, benadryl should produce symptomatic relief in vasomotor rhinitis. The subject was discussed from several points of view in a symposium on the drug by McElin and Horton, Koelsche, Prickman and Carryer, Williams[27] and Code.[2] Williams said that the effect of benadryl on perennial vasomotor rhinitis appeared to be superior to that of nicotinic acid.

Benadryl certainly gives marked relief to many patients, but all rhinologists are familiar with the many instances in which the drug appears to be of no value. Sometimes the side effects—drowsiness or nervousness—are most annoying. This again raises the question as to whether the release of histamine is or is not the cause of the symptoms of allergy. In this respect I can do no better than to quote Code[1]: "In allergic reactions, histamine may produce a dramatic veil of symptoms, behind which lies the damaged cell."

A newer drug, pyribenzamine, appears to exert about the same effects as benadryl. Perhaps the side reactions of pyribenzamine are not so noticeable among some patients as are the side effects of benadryl.

Comment

I have not included a discussion of the treatment of nasal polyps and secondary hyperplastic sinusitis. It is sufficient to say that surgical correction of these conditions is indicated before satisfactory results can be expected from the forms of therapy described herein.

Summary and Conclusions

The relationship of anaphylaxis and allergy has been discussed, together with the theory of the release of histamine during the reactions. The types of therapy based on this theory have been described, and their results in various investigators' hands have been noted.

The syndrome of intrinsic allergy and the encouraging results of nicotinic acid therapy offer a field for further investigation. Many patients who have perennial vasomotor rhinitis can be relieved to varying degrees by nonspecific therapy, including elimination of dust, hyposensitization to house dust, electrocoagulation of the submucosa of the turbinates, elimination of household pets, and cessation of the use of nose drops.

The newer antihistamine drugs, benadryl and pyribenzamine, offer relief to many patients.

Further investigation is needed to determine what lies behind the damage to cells and the release of histamine in the allergic reaction.

ORCHIECTOMY AND HORMONES IN PROSTATIC CARCINOMA

PHILIP F. DONOHUE, M.D.
Saint Paul, Minnesota

CARCINOMA of the prostate has long been regarded as one of the most deadly, if not the most hopeless, diseases affecting the aging male. According to statistical studies, the condition occurs in 17 per cent of men over fifty years of age and in 25 per cent of men over sixty years of age. Unfortunately, the disease is present for a considerable length of time without the knowledge of its victim and may advance to an incurable stage before symptoms develop which lead to examination and discovery. As a result of this insidious character, less than 2 per cent of all the individuals with carcinoma of the prostate consult a physician while the condition is still amenable to a cure. The remaining 98 per cent or more, when first seen by the physician, present various stages of extension of carcinoma. Before the introduction of treatment by castration and the administration of estrogen, the disease advanced until great suffering and disability were experienced, and management of this stage of the disease was entirely a matter of relief of pain, with frequent resort to deep x-ray and opiates. With our present methods of androgen control treatment available, the progress of the disease now may be checked for periods of several months or years and patients with pain and physical disability may return to states of comfort and physical well-being. Such startling results may continue for varying periods. A small number of patients have remained well and without signs of the disease for more than five years, and there is just a possibility of complete eradication of the disease. However, relapse is the rule, as shown by follow-up studies which show the temporary nature of the good results and the recurrence of pain, loss of weight and weakness, ending in death from prostatic cancer. Since its introduction five years ago, this form of therapy has been fully tested clinically and is now firmly established as a simple and effective method of suppressing the painful and disabling effects of metastatic carcinoma of the prostate. Although beneficial results are temporary and the disease is eventually reactivated, many months or even years may be added to life.

Androgen control treatment is a method of completely disposing of the male hormone by castration or by neutralization through the administration of estrogen. The method is based upon the investigations of Huggins who showed that the epithelial cells of metastatic lesions of prostatic carcinoma are directly influenced by androgen. Androgen is a stimulant to the growth of these cells, and consequently, to the spread of the disease. Regression of the metastatic lesions will result when androgen is removed by castration or neutralized by the administration of stilbestrol. Application by Huggins of either of these methods to patients with demonstrable metastasis was followed by immediate subjective and objective improvement.

Before any method of treatment is adopted, every patient with carcinoma of the prostate should be thoroughly examined to determine the extent of the malignancy. The examination should include x-ray survey of the bones of the pelvis, vertebrae, ribs, femurs, x-ray examination of the lungs, and determination of acid phosphatase in the blood. Of particular importance is the examination of the prostate by rectal palpation. Even in early cases the findings are sufficiently characteristic to be strongly suggestive. As the condition advances in the prostate, the changes become more striking and typical and the diagnosis correspondingly easier to make. It is estimated that in 60 or 75 per cent of cases, prostatic carcinoma begins in the posterior lobe, and since this part of the prostate is immediately adjacent to the anterior wall of the rectum, it would seem that a high percentage of early involvement can be discovered by careful rectal palpation frequently carried out in all men over fifty years of age. On examination, the absence of the normal elasticity of the gland and the presence of one or more areas of induration strongly suggest the possibility of carcinoma, and when the induration is marked, there should be little doubt. When the indurated area is limited to the gland substance, and the adjacent structures at the periphery of the prostate are free, the condition may be considered localized and suitable for cure by operation. In some cases moder-

---

Read at the annual meeting of the Minnesota State Medical Association, Saint Paul, May, 1946.

ate degrees of induration are difficult to evaluate. These doubtful cases should be examined periodically, and other possible causes such as prostatic calculi and prostatic inflammation excluded by x-ray studies and examination of prostatic secretion. The nature of the localized induration may remain in doubt until a specimen is obtained for biopsy. This procedure is to be recommended in doubtful cases. Perineal exposure of the posterior surface of the prostate is required, and this permits immediate radical removal of the entire gland and seminal vesicles in the event the examination shows carcinoma.

Eventually the malignant process spreads and involves the entire gland substance and capsule. From the prostate the growth extends upward to invade the seminal vesicles and the base of the bladder. The process may penetrate the capsule, spreading laterally to the pelvis and downward to the membranous urethra. Rectal examination at this stage shows the prostate transformed into a stony hard, irregular, immovable mass attached to the bony pelvis laterally and extending upward beyond the reach of the finger. Spread of the disease beyond the prostatic area occurs by way of the perineural lymphatics to the regional lymphatic glands. Later the bones are involved. The pelvis, sacrum and vertebra are the most frequent sites of the metastasis, but the process may also be found in the ribs, femurs or humeri. Lesions may appear in the lungs and in the lymphatic glands of the neck and the groin. Metastatic extension to the spinal cord may occur with motor and sensory paralysis of the lower extremities.

The purpose of treatment in carcinoma of the prostate differs with the stage of the disease. In cases in which the growth is well localized within the prostatic capsule, complete eradication of the disease is possible, and this should be the aim of treatment. At present, such cases are encountered infrequently but can be expected to be recognized in increasing number when more people are aware of the possibility that carcinoma of the prostate may exist in any man past fifty regardless of the absence of suggestive symptoms. With routine rectal examination in all men past fifty, more cases will be found suitable for radical perineal prostatectomy, which is the only way cancer of the prostate can be cured.

When the malignant process has spread beyond the prostate, cure of the disease is impossible, and in this event the purpose of treatment is to relieve or diminish suffering and to prolong life. Great suffering and physical disability occur sooner or later in almost every case and require androgen control treatment. The optimum moment to begin treatment and the choice between estrogen and castration will depend upon the clinical picture and the findings on examination of the patient. From the experiences of others and that of the writer with hormonal treatment in advanced incurable prostatic cancer, several facts have emerged which are helpful in obtaining the greatest relief for the longest period of time. These observations indicate that responses to the oral use of estrogen (stilbestrol) and to castration are similar and equal, although somewhat more rapid with castration. Relief of pain, regression of metastatic lesions, return of vigor and physical capacity follow either method. These benefits are temporary and ultimately disappear. Patients relapsing following good results from estrogens will often recover following castration. Relapses following castration may or may not improve when given estrogens. Since neither estrogens nor castration prevent the development of metastasis, both should be withheld during early stages of the disease. The full benefit of both forms of treatment for the longest periods possible are then available in the metastatic stage. Stated in another way, androgen control treatment achieves the longest possible life survival for the patient when used only for the relief of symptoms of metastatic carcinoma of the prostate and to check or eradicate demonstrable metastatic lesions. The effect of the treatment may be followed by frequent determination of the serum acid phosphatase. High readings are suggestive of metastatic activity, but low or normal readings may be of no value.

Clinically, incurable carcinoma of the prostate is encountered in either one of two stages of the disease. In the first are the patients seeking relief because of urinary obstruction. They show involvement of the prostatic capsule and varying degrees of local extension of the malignancy but have no symptoms of metastasis or evidence of metastatic lesions on examination. These patients require no androgen control treatment at that stage but are examined at frequent intervals to discover the spread of the disease. This includes blood acid phosphatase and x-ray examinations of the bones.

In the second group are individuals with definite symptoms of metastasis or with demonstrable metastatic lesions. These patients require immediate androgen control treatment. Treatment is begun with stilbestrol in doses up to 10 mg. daily, which may be reduced to 2 or 3 mg. when relief is established. The effect of stilbestrol is evaluated by periodic examination, with particular reliance on the x-ray findings in the bones. The return of pain or the increase in size or number of metastatic lesions is evidence of definite relapse from the benefits of stilbestrol, and castration is then indicated. Transurethral resection may be required to relieve obstruction developing in either group.

The reports of three cases will illustrate some of the problems encountered in treatment.

Case Reports

Case 1.—M. T., aged sixty-three, had no general or urinary symptoms when seen on January 14, 1943. An indurated area on the posterior lobe of his prostate was a chance finding during a search for a focus of infection to explain his keratitis. The periphery of the gland and the seminal vesicles were normal. The acid phosphatase was normal, and an x-ray showed no evidence of bone metastasis. The diagnosis was probable carcinoma of the prostate. A biopsy was indicated.

On January 20 biopsy findings showed carcinoma, and a radical perineal removal of the prostate and the seminal vesicles was done. The specimen weighed 43 gm. and had a fairly large indurated area surrounded by a smooth intact capsule. The pathological report was adenocarcinoma of the prostate with normal seminal vesicles.

When seen on April 22, the patient was feeling fine, and his acid phosphatase was normal. X-ray revealed a questionable metastasis in the pelvis. On September 22 x-ray examination showed diffuse metastases throughout the pelvis. The patient had no symptoms, and his urinary control was improving. The acid phosphatase was still normal. Castration was performed on October 4, 1943. X-ray examination on January 6, 1944, showed that the metastases in the pelvis were unchanged. Over a year later, on March 7, 1945, the patient presented no complaints. His urinary control was satisfactory, although occasionally he had an escape of a small amount of urine in the late afternoon. The osteoblastic metastases in the pelvis were shown by x-ray to be definitely disappearing.

An x-ray examination the following year, on March 13, 1946, demonstrated that complete clearing of the osteoblastic metastases in the pelvis had occurred. No signs of them were visible. Chest x-ray findings were also normal. On May 15, 1946, forty months after the diagnosis and radical perineal prostatectomy, the patient felt healthy and vigorous.

This case emphasizes the importance of periodic rectal examination of the prostate in all men after the age of fifty. This sixty-three-year-old man had had no complaints referrable to the prostate and discovery of the malignancy was something of an accident. Unfortunately spread of the disease had occurred although not demonstrated until nine months after prostatectomy. It may be assumed that the condition could have been discovered while in a curable stage if periodic rectal examination had been made. Castration was performed when metastatic lesions were demonstrable and the disappearance of these lesions after two and a half years is striking. Eventual relapse is expected.

Case 2.—K. D., aged sixty-four, complained of sciatica and pain in the sacrum when seen on November 29, 1941. He had a slight amount of urinary difficulty. Residual urine was found to be 75 c.c. His prostate was moderately enlarged and had two hard areas extending to the periprostatic tissue, with induration of the base of the bladder and the right seminal vesicle. X-ray examination revealed a normal pelvis. The diagnosis was carcinoma of the prostate extending beyond the gland.

On April 9, 1942, the sacral and sciatic pain had increased. Stilbestrol was administered and gave relief. On May 15 the acid phosphatase was measured at 20.7 units, and x-ray examination showed metastases in the pelvis and femurs. A month later, on June 15, the pain had increased severely, and the patient was unable to walk or move his legs. On neurologic consultation a metastatic involvement of the lumbrosacral area of the spinal cord was diagnosed. X-ray examination further revealed metastases in the ribs and in the thoracic spine. Castration was performed.

By July 29 the patient felt comfortable and was able to walk alone fairly well. His clinical improvement was amazing, and by November 23 he had no pain and was able to walk satisfactorily with a cane. His appetite was good, and he had returned to work. Rectal examination showed that the prostatic hardness had disappeared.

On January 12, 1943, six months after the castration, the patient complained that the pain in his right hip had returned two weeks earlier. It seemed to be aggravated by standing. He was confined to bed and given 4 mg. of stilbestrol daily. He had had a moderate weight loss, and the lymph glands in his neck were enlarged. On March 30 an x-ray showed that he had developed a pathologic fracture of the right femur. By November 29, 1943, he was quite cachectic and was receiving frequent opiates for pain. X-rays revealed extensive metastases to the ribs and the left shoulder. On January 13, 1944, twenty-six months after diagnosis, and eighteen months after castration, the patient died.

In this case the disease was rapidly destructive, and the response to androgen control treatment short or incomplete. Stilbestrol was administered for symptoms suggestive of metastasis at a time when acid phosphatase and x-ray studies were normal. Stilbestrol failed to check the development of metastases and paralysis due to involvement of the spinal cord. Almost complete symptomatic recovery followed castration but lasted only six months and did not prevent a pathologic fracture.

Androgens are found in the urine in cases relapsing after castration, indicating extragonadal source of the male hormone. These sources are quiescent for variable periods, but eventually become activated, releasing androgens which stimulate the metastatic process. The nature of the activating agent is unknown.

Case 3.—W. S., aged seventy-one, was seen on July 12, 1942, complaining of urinary difficulty, passage of blood from the rectum, and lumbosacral pain. He had a large mass in the right groin. Rectal examination disclosed a large irregular mass involving the anterior rectal wall and the upper rectum. X-ray studies demonstrated a deformity of the rectum, as well as extensive metastases in the pelvis and vertebrae. The diagrosis was metastatic carcinoma of the prostate with urinary obstruction. A transurethral resection and castration were performed.

On August 30 the mass in the groin was diminishing, the pain was less severe, and he was no longer passing blood from the rectum. X-ray examination on September 14 showed that there had been an increase in the metastatic carcinoma in the pelvis and in the lumbar vertabrae. The mass in the groin had disappeared.

On January 24, 1944, one and one-half years after diagnosis and castration, improvement was noted in the bony changes in the pelvis and vertebrae. The patient was seen again on May 16, when he complained of pain in the rectum and stated that he was having frequent bloody stools. A colostomy was performed, followed by a posterior resection of the rectum. The pathological diagnosis was adenocarcinoma of the rectum. The patient made a good recovery and returned to business.

He was in good health when seen on May 15, 1946, almost four years after castration had been performed. He had no pain, and his colostomy was functioning well.

Here a large metastatic mass in a lymphatic gland disappeared soon after castration. Bony metastases at first increased but later a definite regression occurred. He has recovered from removal of the rectum for carcinoma, attends to business and lives comfortably four years after castration.

Summary

1. Androgen control treatment is not a cure for carcinoma of the prostate.

2. It is, however, an effective method of suppressing the metastatic stage of the disease.

3. Stilbestrol and castration are equally effective.

4. Neither stilbestrol nor castration prevents metastasis and should be withheld until metastasis has occurred.

5. Pain, x-ray changes in the bones, and elevated serum acid phosphatase are indications for androgen control treatment.

6. Return of comfort for the longest possible period of time is obtained when stilbestrol is used first and castration is withheld until the effectiveness of stilbestrol has diminished.

7. A gain in life survival of eighteen months to two years is the average, but the period may be considerably longer in some cases.

8. All men over fifty years of age should have rectal palpation of the prostate at least once a year.

9. Suspicious areas of induration may call for biopsy.

10. Radical perineal prostatectomy is indicated when carcinoma is found, and this is the only way carcinoma of the prostate can be cured.

PENICILLIN

The topical use of penicillin ointment is becoming a standard form of therapy in industrial clinics. All clinical therapeutic trials of the past several years have demonstrated the effectiveness of this new antibiotic agent when incorporated in a suitable ointment base and used locally in the treatment of impetigo contagiosa, sycosis barbae, infectious eczematoid dermatitis, ecthyma, furunculosis, carbuncles, chronic ulcers of the extremities, and other susceptible infections of the skin. The treatment of staphylococcic and streptococcic local infections of the skin has produced the most dramatic results. It has proved to be of value in the treatment of secondarily infected lesions, which are superimposed on dermatophytosis, acne vulgaris, and contact dermatitis.

Penicillin is not a cure-all for skin infections. It will not replace accurate diagnosis and other specific therapy, nor will it replace surgery and débridement. But, when used locally, penicillin is an ideal antiseptic.†—*New York J. Med.*, Feb. 15, 1947.

MYCETOMA OR MADURA FOOT

Report of Cases Including One Case of Maduromycosis of the Hand

HENRY W. MEYERDING, M.D., and J. A. EVERT, JR., M.D.
Rochester, Minnesota

A MYCETOMA is a chronic granulomatous lesion caused by a fungus infection and characterized by indolent inflammatory swellings containing multiple sinuses which may penetrate into the bone and discharge a substance containing tiny granules. The lesion is most commonly found in the feet, where it has been called Madura foot. The disease is rare in the United States, although it is fairly common in certain parts of the tropics. In a recent review of the subject, Burns, Moss and Brueck collected reports of thirty-five cases observed in the United States and Canada and reported three additional cases. More recent case reports have been presented by several others, including Wood, Clough, Gottlieb, Hatch and Wells, Peters, and Symmers and Sporer. It is the purpose of this article to present data on three cases of mycetoma of the foot and one case of mycetoma of the hand which have been observed at the Mayo Clinic.

The disease is endemic among out-of-door workers in such hot dry tropical regions as southern India, where it was first described, Mexico and the southwestern part of the United States. The majority of the cases seen in North America have been found in the latter region. Among 100 successive patients observed in India, ninety-one were agricultural workers. Among the thirty-eight patients in the United States, twenty-one were laborers or farmers. Physicians who have seen much of the disease comment on its frequency among people who go barefoot. In the majority of cases, the patient has been able to recall some sort of trauma, such as a laceration or contusion of the foot, which occurred several months prior to the onset of symptoms. Such trauma probably furnished the site through which the organism gained entrance.

The fungi found in cases of mycetoma may be any of a number of different species belonging to the botanical orders Actinomyces or Hyphomycetes (fungi imperfecti). Lesions caused by fungi of the former order are called actinomycoses and lesions caused by fungi of the latter order are called maduromycoses. In this country, actinomycoses are far less common in the feet than in other parts of the body, while maduromycoses are seldom found elsewhere than in the extremities. For practical purposes, the pathologic lesion of mycetoma is the same regardless of the type of infectious agent.[2,4,5,7,8]

A mycetoma is characterized clinically by its chronicity, which may be measured in terms of years, and by its relatively painless course. The lesion may involve a certain region extensively but it seldom spreads to other parts of the body. It has been described as a small subcutaneous swelling which is somewhat tender and has an indistinct base fixed to the underlying tissues. The swelling may be nodular or may appear to be an abscess or vesicle. After a variable period, from a few weeks to many months or even years, the swelling softens, breaks open and discharges a serous fluid containing small yellow, black or red granules which are fungus colonies and which are pathognomonic of the condition. The sinuses thus formed usually heal within a few days but from time to time other sinuses appear singly or in groups until the involved region is covered by them. Ultimately the swelling spreads until the whole part assumes a characteristic globoid appearance which is manifest in the foot as great thickening and loss of the plantar concavity. The lesion involves the subcutaneous tissues primarily but it may extend into the bones in the later stages. On pathologic examination the lesion is seen to consist of a honeycomb of sinuses surrounded by dense fibrous tissue. The process rarely spreads beyond the extremity and the patient's general condition may remain good. In 100 successive cases reported by Bocarro, the lesions were distributed as follows: ninety-three on the foot, three on the hand, two on the leg and one each on the scapular and sacroiliac regions.

Roentgenograms have shown no change until late in the course of the disease, when changes characteristic of the spread of a contiguous infectious process appear. The bone then shows periostitis, moth-eaten rarefaction and, ultimately, destruction with osteomyelitis and ankylosis.

Dr. Meyerding is from the Section on Orthopedic Surgery, Mayo Clinic, and Dr. Evert is a Fellow in Surgery, Mayo Foundation, Rochester, Minnesota.

In most of the cases which have been reported, the disease has progressed steadily regardless of treatment. While the classic therapeutic agent, potassium iodide, has been of little benefit, sulfonamide therapy has been followed by temporary improvement in two cases reported recently. Adequate amounts of the new antibiotics have not, to our knowledge, been employed in the treatment. We believe that streptomycin and penicillin may be of value and should be given a thorough trial in the early stages before extensive changes in the bones have occurred. In most cases surgical excision has been the ultimate recourse. The excision should include a wide region of tissue about the diseased part, since local excision has frequently been followed by recurrence. Since the patient's general health is seldom affected, there apparently is no urgency about surgical treatment, and amputation of the extremity is resorted to as a rule only after years of recurring sinus formation with marked swelling and repeated periods of disability.

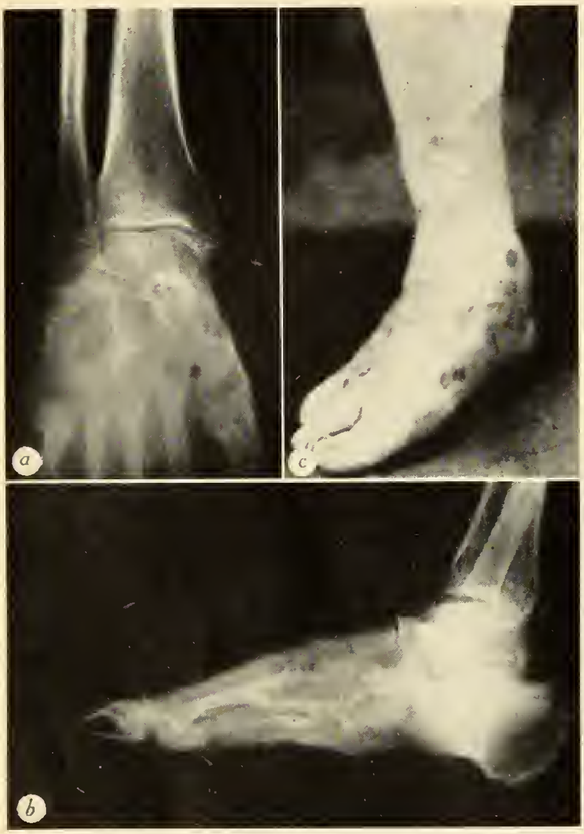

Fig. 1 (a) Anteroposterior roentgenogram of the right foot and ankle shows extensive osteomyelitis involving the tarsal, metatarsal and phalangeal bones, with ankylosis. (b) Lateral view shows involvement of the astragalus, the os calcis, tarsus and metatarsus and phalanges with destructive changes and extensive ankylosis (this is a picture of long-standing osteomyelitis and ankylosis). (c) Scars and discoloration with thickening of the foot in a case of long-standing Madura foot.

Report of Cases

Case 1.—A railroad car repairman, forty-four years of age, reported for examination at the clinic because of pain in the right foot of eleven years' duration. He had been a resident of Iowa for many years. He stated that about fourteen years prior to his admission a weight had fallen on the dorsum of his right foot. Three years afterward he had noticed a pain in the distal portion of the right foot, followed by a swelling surrounded by a region of inflammation. A month later, swelling broke down into multiple draining sinuses which healed within a few days. Similar episodes recurred at irregular intervals several times a year. Each time the sequence of symptoms was the same, starting with a rather sudden pain followed by a swelling which localized into multiple pustules. When the pustules opened, they discharged a thick yellow or red material containing "small white lumps." The foot became somewhat larger after each episode. Four months prior to the patient's admission, the most recent swelling had occurred after a blow on the foot. During the course of his illness, he had consulted numerous physicians, had received various forms of treatment and had had two operations on the foot. He further stated that eleven years prior to his admission three masses of tissue had been removed from the dorsal and medial aspects of the foot. Nine years before admission a piece of bone had been removed from the dorsum, and the plantar aspect of the foot had been drained. Cultures had been reported negative at that time.

Physical examination showed the patient to be a well-developed and well-nourished man in no distress with a temperature of 98.2° F. The entire right foot was swollen, indurated and covered by multiple small scars, some of which contained open sinuses with "punched-out" openings about 1 mm. in diameter. The swelling extended a short distance proximal to the malleoli. The patient had limited flexion and extension of the ankle and he was unable to invert or evert the foot. There were palpable lymph nodes in the right inguinal region. One of us made a clinical diagnosis of Madura foot on inspection and advised cultures for mycetoma.

The examination also disclosed the results of urinalysis to be normal except for some pus cells; the flocculation reaction was negative; the concentration of hemoglobin was 14.2 gm. per 100 c.c. of blood; the sedimentation rate (Westergren) was 48 mm. per hour; roentgenograms of the thorax were normal. A culture of the discharge from the foot showed a fungus, which was identified as Monosporium apiospermum. The roentgenograms of the right foot showed "osteomyelitis" involving the tarsus, the os calcis and the proximal portions of the metatarsal bones, with destruction and ankylosis of the regional joints.

The patient was not particularly disabled and was permitted to return to his work. He was advised to consider amputation if he should become severely incapacitated (Fig. 1, a, b and c).

Case 2.—A man, thirty-two years of age, came for examination because of a swelling of the right foot, which had been present for ten years. The patient was a laborer who lived in Indiana. Ten years prior to his admission, while at work, he had noticed a gradual onset of aching pain in the dorsum of the right foot. Eight and a half years prior to the examination he had noticed the right ankle had become swollen, painful and warm, and the skin had a purplish discoloration. The pain and swelling partially resolved after about one week but thereafter the patient had similar attacks at irregular intervals three to five times each year. Six years before coming to the clinic he had had a red indurated area on the dorsum of the foot which opened and discharged a thick yellow material for several weeks. Similar sinuses appeared in various parts of the foot thereafter.

Examination showed the patient to be a healthy young man in no distress. The temperature was 98° F. The right foot was warm and swollen, and the skin about the ankle was indurated. There were numerous depressed pigmented scars over this area, and on the posterior aspect of the ankle there were two firm red swellings. The remainder of the examination revealed negative results of urinalysis and flocculation test; a concentration of hemoglobin of 14.4 gm. per 100 c.c. of blood and a leukocyte count of 7,100 per cubic millimeter of blood; the sedimentation rate (Westergren) 10 mm. per hour. The roentgenograms of the right foot and ankle did not reveal any significant changes. A biopsy of the lesion at the site of the two small abscesses on the medial aspect of the ankle was performed; thin yellowish gray pus was removed. Microscopic examination revealed granulomatous tissue containing tiny abscesses in which were filamentous masses of fungi. These fungi had no chlamydospores and the organism appeared to be one characteristic of a maduromycosis rather than an actinomycosis. Attempts to culture the organism were unsuccessful.

The patient was given roentgen therapy and potassium iodide was prescribed. He was advised to have amputation of the foot if the condition seriously handicapped or disabled him.

Case 3.—A woman from Texas, forty-eight years of age, reported for examination because of drainage from the left heel of three years' duration. She stated that about three and a half years prior to her admission at the clinic she had had a fall from a ladder and had struck the ground firmly with her left heel. The heel had become painful and discolored following this and was painful whenever she walked. Six months later the heel had become red and swollen and her physician had incised the plantar surface with negative findings. Some weeks later a spontaneous discharge appeared and formed a sinus, which soon healed, but similar swellings and drainage appeared about the ankle at one-month to two-month intervals thereafter. From time to time various treatments, including incision, curettage, excision, cautery, local applications and roentgen therapy, had been tried without noticeable effect. The patient commented that the material from the sinuses occasionally contained masses which looked like "popcorn." She had little pain and was able to walk on the heel whenever an abscess was not forming. A culture which had been taken six months prior to her examination at the clinic was reported as showing "Madura fungus."

Examination showed the patient to be a well-developed healthy-looking person in no distress. The temperature was 99° F. The left heel contained three sinuses, one of which was exuding a thick purulent material. About the sinuses was an area of erosion and ulceration. The plantar surface of the heel was moderately tender. The foot was held in a position of equinus and the calf was slightly atrophied. The urinalysis and the flocculation test gave negative results. The concentration of hemoglobin was 11.6 gm. per 100 c.c. of blood; erythrocytes numbered 4,290,000 and leukocytes 5,100 per cubic millimeter of blood. The sedimentation rate (Westergren) was 27 mm. per hour. The roentgenograms of the thorax were normal. The roentgenograms of the left foot showed some cortical irregularity of the os calcis and osteitis in the posterior inferior portion. Repeated cultures from the sinuses of the foot failed to demonstrate any fungi, although Staphylococcus aureus and Pseudomonas were found. A biopsy of the heel was performed. The subcutaneous tissue was found to contain several necrotic regions and proved to be involved in a chronic granulomatous process containing mycotic fungi with morphologic characteristics of Actinomyces. One week later the involved region of the left heel was widely excised. It was found to contain multiple subcutaneous abscesses which extended deeply to involve the underlying bone. After this operation, the incision healed well and a split-skin graft was applied. Four weeks later, however, several tender areas appeared in the base of the incision, from which there was a purulent drainage. Three weeks afterward the leg was amputated at the junction of the upper and middle thirds of the left tibia. The postoperative convalescence was uneventful and the patient returned home in good condition.

Case 4.—A merchant, thirty-nine years of age, a native of Mexico, came to the clinic for examination because of a swelling on the palm of the left hand of seventeen years' duration. He stated that seventeen years prior to consultation, at a time when he was working on a farm, a pimple had developed on the left palm. The lesion gradually enlarged without particular pain and discharged purulent material from time to time. It had never healed. Two operations four and three years previously and two courses of roentgen therapy two years previously had not been beneficial.

Examination showed the patient to be a well-developed and well-nourished man in no distress. The temperature was 98° F. The left hand was thicker than the right and there was an indurated area over the base of the left first metacarpal bone in which there were about ten small draining sinuses from which exuded purulent material containing granules. The urinalysis and the flocculation test gave negative results. The concentration of hemoglobin was 16.3 gm. per 100 c.c. of blood; leukocytes numbered 8,000 per cubic millimeter of blood. The roentgenograms of the thorax were normal. The discharge from the hand was found to contain pinhead-

Case Report

INTESTINAL ASCARIS DIAGNOSED ROENTGENOGRAPHICALLY IN MINNESOTA

R. S. LEIGHTON, M.D., and R. J. WEISBERG, M.D.
Minneapolis, Minnesota

During the last twenty-five years, a number of reports have been published of the diagnosis of roundworm infestation by means of the x-ray examination. Due to the return of a great many veterans from tropical theaters, ascaridiasis is now appearing in the North Central United States, where it would hardly have been considered prior to the recent war. The case herein described is reported not as something new but because it is felt worth while under the circumstances to call attention of physicians to this new problem and to re-emphasize the little known fact that many cases may be diagnosed only by means of x-ray study.

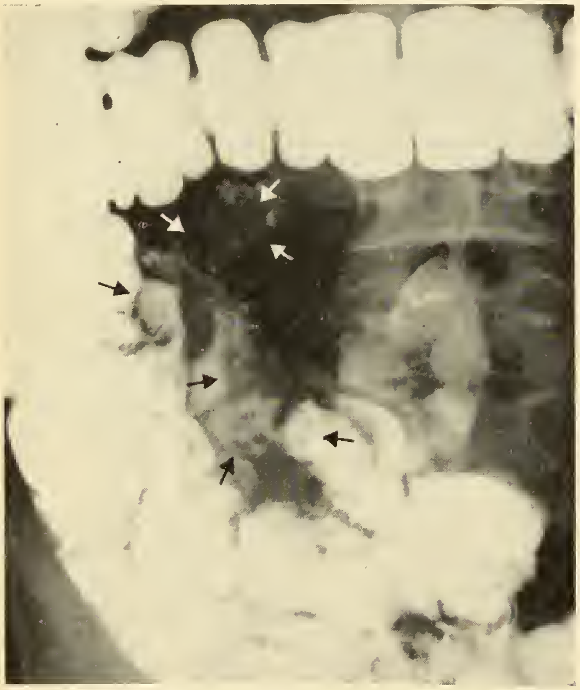

Fig. 1. Roentgenogram following barium enema shows ascaris in terminal ileum. The worm produces a bandlike area of decreased density of sinuous character indicated by arrows.

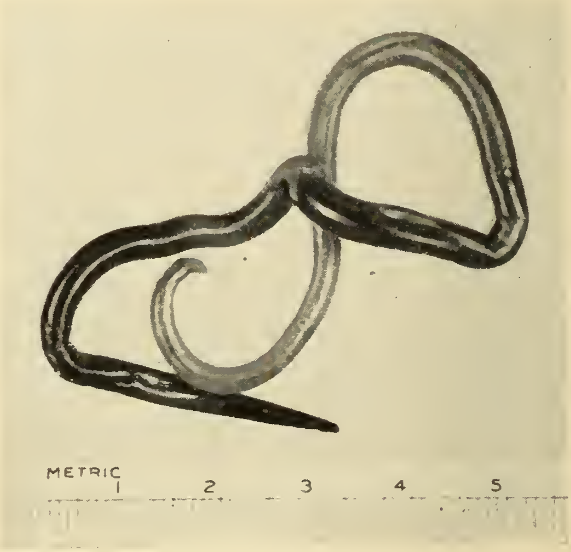

Fig. 2. Photograph of worm following expulsion.

Case Report

R. W., a thirty-one-year-old veteran who had had service in the Southwest Pacific, reported to the Veterans Hospital in Minneapolis on September 18, 1946, complaining of diarrhea and occasional low abdominal cramps. The onset of his illness apparently dated back to March, 1945, at which time he was treated for amebiasis in an army hospital in the Philippines. His symptoms cleared up after one month's treatment, and he was well until September, 1945, when his difficulty recurred. He was studied in an army hospital at that time, and stool studies were negative for ova and parasites. He was discharged with a diagnosis of anxiety state and psychoneurosis. Since that time he continuously had mucus but no gross blood. Occasional cramps was the only other symptom.

He was studied during the summer of 1946 at the Minneapolis Veterans Hospital, at which time the stools were found to be free of ova and parasites, and a proctoscopic examination to 25 cm. revealed a normal colon. A barium enema done on July 1, 1946, revealed a negative shadow in the terminal ileum which was reported as probably representing a single large ascaris (Fig. 1). An upper gastrointestinal x-ray study was normal. Because of nervousness and diarrhea he was hospitalized on September 18, 1946, for further investigation.

Physical examination was entirely normal except for some slight tenderness in the right upper quadrant of the abdomen. Laboratory workup, including stool examinations, yielded nothing of note.

Because of the positive x-ray report for ascaris and the lack of any other positive findings, it was decided to conduct a therapeutic test in spite of the absence of ova in the stool. After preparation with magnesium sulfate, one gram of hexylresorcinol was given on an empty stomach. Twenty-four hours later another dose of mag-

nesium sulfate was given, and an 8-inch male ascaris lumbricoides (Fig. 2) was recovered from the stool. Full clinical recovery occurred immediately following expulsion of the worm.

Discussion

Diagnosis of ascaridiasis was first made by means of x-rays by Fritz in 1922. In 1925 Forsell showed definitely the value of roentgen examination in this disease and stated that if the infestation was by male worms, x-rays offered the only available means of definitive diagnosis. Fiessly in 1942 reported a case in which a single male worm was found by x-ray examination and another in which the diagnosis was made in a patient whose stools were normal.

Our case again demonstrates the value of the examination in the frequent cases of single male infestation. It should be pointed out that whereas the worm is clearly seen on the barium enema films, it could not be made out when the barium was given by mouth. Several investigators report visualization with oral barium. When the disease is suspected, it cannot definitely be ruled out by examination by either route. Only the positive findings are of real significance.

MYCETOMA OR MADURA FOOT

(Continued from Page 409)

sized black granules which proved to be colonies of fungi belonging to the genus Madurella. On biopsy, the skin of the left thenar eminence was reported to be typical of maduromycosis. The patient was given a course of roentgen therapy and potassium iodide, with temporary improvement. Three years after the examination, the patient's left index finger and the involved portion of the palm were excised elsewhere. He was then free of symptoms until eighteen months later when there was recurrence of the disease. In a letter received four and a half years later, the patient wrote: "I am reconciled to amputation."

Comment

An analysis of these cases shows that two of the patients were inhabitants of the north central part of the United States who had never been to the tropics but whose occupations kept them out of doors. One patient was a native of Texas. The mycetoma of the hand, which is so rare a condition as to be a curiosity, was found in a patient who was a native of Mexico and who had been doing agricultural work at the time he acquired the disease. Two of the patients who had lesions of the foot gave a definite history of antecedent trauma. The infectious agent was found to be Monosporium apiospermum (order Hyphomycetes) after study of cultures in one case. In the other two cases, the morphologic examination revealed an organism of the order Hyphomycetes once, an organism of the order Actinomyces once, and gave an equivocal result once. Positive identification of the fungi is a matter of some scientific interest in this rare condition, but it depends on difficult cultural techniques and it is not essential to the diagnosis of the condition. These three cases of Madura foot and the case of maduromycosis of the hand have been presented in order to call attention to an unusual suppurative condition characterized by a granular discharge, the course of which is chronic and relatively painless.

History of Medicine In Minnesota

NOTES ON THE HISTORY OF MEDICINE IN FILLMORE COUNTY PRIOR TO 1900

By NORA H. GUTHREY
Mayo Clinic
Rochester, Minnesota

(Continued from March issue)

Don J. Lathrop was born at Aurora, New York, 1851, was educated in the local district schools, and at the age of nineteen years entered the Medical School of the University of Buffalo, New York, from which he was graduated in February, 1872. Millard Fillmore, later to be President of the United States, was at that time chancellor of the university, and from his hands Dr. Lathrop received his diploma.

In the spring of 1872, just out of medical school, Dr. Lathrop settled in Granger, Bristol Township, Fillmore County, Minnesota, succeeding in practice Dr. Henry Jones, who was moving to Preston. In Granger he spent the remainder of his life, the only resident physician and surgeon in the village. For a few years, beginning in 1872, Dr. Lathrop owned and operated a drug store, which in 1877 he sold to a Mr. Andrews. In a business directory of that period he was listed as physician, druggist and notary. Records suggest that he was an able and progressive member of his profession, for in 1880 he was one of the eleven physicians in the county who replied to the request of the State Board of Health for help in compiling statistics on diphtheria in Fillmore County in the period from November 1, 1879, to November 1, 1880.

On July 4, 1882, Dr. Lathrop, in firing a patriotic salute, was terribly injured and disfigured about the face by the premature discharge of the cannon; one eye was destroyed and he almost completely lost the sight of the other. In spite of his handicap he thereafter carried on his medical practice and, it has been said, even attempted to perform surgical operations. In a news item of November 18, 1886, it appeared that a few days previously Dr. Frank (perhaps Dr. Adam Frank, of Iowa), had "skillfully performed the operation necessary to insert a pair of artificial eyes which any stranger would not recognize as unnatural. The change in Dr. Lathrop's looks is marvelous. His neighbors and friends call it wonderful and join in thanks to Dr. Frank, whose professional work uniformly gives satisfaction."

Dr. Lathrop lived until May 2, 1888. (This date is from the records of the Masonic Blue Lodge, of Preston, an order which Dr. Lathrop joined on September 8, 1876.) He was succeeded in practice in his community, as has been told, by Dr. J. Herbert Darey, newly arrived from the East.

Dr. Leprohon, according to a business directory of 1882-1883, was in Lanesboro, Fillmore County, in those years; in succeeding volumes of the same work his name did not appear. Reference to official medical directories of Minnesota disclosed that R. E. Leprohon in 1879 was graduated from the

Medical Department of the University of Bishops College, Canada, and that on July 31, 1885, two years after the passage of the Medical Practice Act of 1883, Dr. Leprohon, then living in La Crosse, Wisconsin, was licensed to practice in Minnesota, and received state certificate No. 1088 (R). In 1907, and probably much earlier, Dr. Rodolphe E. Leprohon, a graduate of the Medical Department of the University of Bishops College in 1879, was living in Montreal, Quebec, Canada.

Thomas Little was one of Fillmore County's earliest physicians, inasmuch as he was established in the thriving little village of Elliota, Canton Township, prior to 1858. Elliota, platted four years earlier by Captain Julius W. Elliott, its first settler and first postmaster and blacksmith, was an important mail station at the crossroads of several stage lines and the home of various business enterprises.

In this hopeful place, which was to suffer disappointment of its ambitions, Dr. Little opened offices on Saint Paul Street and published a professional card which declared him to be physician and surgeon and dealer in drugs and medicine, paints, oils and so forth.

After 1887 Dr. Little practiced in Minnesota under an affidavit; some time between 1887 and 1890 he moved from the state to Dickinson County, Iowa, which is just across the line from Jackson County, Minnesota.

Andreas (Andrew) Pederson Lommen, son of Peder J. Lommen and Maria Arntson Lommen, was born at the farm home in Spring Grove Township, Houston County, on May 10, 1867. Peder Lommen, a native of Norway, came to America in 1851 and for two years farmed in Dane County, Wisconsin, before settling in Houston County. Marie Arntson came with her parents from Norway to Houston County in 1861. Mr. and Mrs. Lommen were married in that county and there spent their lives. They had four children, all of whom were fine citizens: Christian, Dean of the Medical Department of the University of South Dakota, in Vermillion, until his death; Andreas; Sarah Lommen (Mrs. Ning) Eley, of Des Plaines, Illinois; and Belle, a retired teacher, formerly on the faculty of the University of Iowa, of late years residing in San Diego, California.

Andreas Lommen, when a young boy, was a pupil in the rural schools near his home and in the graded schools of the village of Spring Grove; later he studied for two years at Gales College, in Galesville, Illinois, from which he was graduated. After teaching rural school in 1890 and 1891 he entered the University of Minnesota, taking one year of academic work before enrolling in the medical school, from which he was graduated in June, 1895. Licensed in the same month to practice medicine in the state, he at once established himself in Mabel, Fillmore County, not far from his boyhood home. The successful practice which he built up in his two years in the community was a prelude to more extensive work in another section of the county. In 1897, favorable opportunity offering in Lanesboro, he moved to that village, where for the next forty-five years he was an able and kindly physician, loved and honored, true to the ethics of his profession, and a willing and no less able public servant.

A man of practical wisdom and foresight, Dr. Lommen was of value in many positions of responsibility. He held office as county physician and county health officer, was active in the county, state and national medical associations, and was chairman of the board of education, and for nine terms was mayor of Lanesboro. He was a member of the Bethel Lutheran Church, the Independent Order of Odd Fellows and the Yeomen, charter member and medical adviser of the Sons of Norway and charter member of the American Legion. During World War I he was a captain in the Medical Corps of the United States Army, stationed at Camp Shelby, Mississippi, until his honorable discharge in 1918. His interests outside his professional and civic life lay in his home and family, his books, garden and farm. In his long years in Lanesboro he saw many physicians come and go. Two names, like his own, that are identified with the welfare of the community, beginning prior to 1900, are those of Dr. Johan C. Hvoslef (1839-1920), who settled in Lanesboro in 1876, and Dr. Frederick A. Drake (1870-), in Lanesboro since 1896.

Andreas Lommen on June 3, 1897, was married to Stella Johnson, daughter of Rasmus and Maria Hellickson Johnson, of Newburg, a village near Mabel. Dr. and Mrs. Lommen had four children, one of whom, Doris Estelle, died young. Of the three who were living at the time these notes were compiled, Robert M. Lommen, an electrical engineer, was in Milwaukee, Wisconsin; and Helen M. Lommen, a teacher, and Andrew Paul Lommen, an attorney, were in Lanesboro. After the entrance of the United States into World War II, Andrew Paul Lommen became a lieutenant in the administrative branch of the United States Air Corps, stationed at Tampa, Florida. A grandson of Dr. Lommen is Paul Warren Lommen.

In gradually failing health for more than a year before his death, Dr. Lommen spent the last few weeks of his life at the Veterans Hospital at Wood, Wisconsin, where he died on September 16, 1942, at the age of seventy-five years. The cause of death was stated as cerebral thrombosis with contributory heart disease, coronary arteriosclerosis with myocardial damage and insufficiency. Burial was in Lanesboro.

T. E. Loop was one of the earliest physicians in Fillmore County, established there perhaps in the middle or late fifties. Search has added nothing to the solitary known fact that he was one of the founders and the first secretary of the Fillmore County Medical Society, which was organized in the office of Dr. Lafayette Redmon, at Preston, on October 17, 1866. That Dr. Loop, then of Spring Valley, was one of this choice group of six physicians drawn from various parts of the county, is presumptive evidence of his ability, intelligence and co-operative spirit.

George Allen Love was born on March 3, 1850, at Woodstock, McHenry County, Illinois, the son of Robert Love and Agnes Dixon Love, both of whom were natives of Glasgow, Scotland. Shortly after their marriage Mr. and Mrs. Robert Love, intent on a home in the Middle West of America, came over from Scotland in a sailing vessel. They first settled in Illinois, later for several years were in and near Manchester, Iowa, and finally moved to Minnesota, in June, 1856, to take a homestead in York Township, Fillmore County. George was then six years old. The other children, all sons, were William, Robert, John and Andrew. In later years William and Robert managed the home farm, John became a druggist, and Andrew a teacher and manager of a teachers' agency in Fargo, North Dakota.

George Love began his formal education at Liberty School in York Township and in 1867, then seventeen years old, he entered the public schools of Preston, to study for three years. Beginning in 1870, he studied medicine for more than a year in the office of Dr. John A. Ross, of Preston, preparatory to entering the Bennett Eclectic College of Medicine and Surgery, in Chicago. After his graduation late in 1874 with the degree of doctor of medicine, he practiced his profession for a few months in the village of Whalen and then for two years was in partnership with Dr. Ross in Preston. Their professional card, which appeared in the *Fillmore County Republican* for January 8, 1875, set forth that Ross and Love, physicians and surgeons, had their office on Main Street, just in rear of the post office, that the office was open day and night and that all calls were promptly attended to.

In 1876 Dr. Love began the independent practice that was to continue for fifty-four years. On December 31, 1883, under the new law on medical practice, he received state certificate No. 669 (E). At this period his office was "three doors south of Tibbetts' Drug store, upstairs." He worked alone until 1912, when he was joined by his son, Dr. George R. Love, in a partnership which was to last eighteen years. In the fifty-six years of his professional career many medical practitioners came and went in the village and the community. Among the best known who were in Preston prior to 1900 were John A. Ross, Henry Jones, Lyman Viall, Charles H. Jacobson and James H. Phillips.

George Allen Love was the typical country doctor in the highest tradition, medical practitioner, counsellor, friend, and to all relationships he brought manners that were not only courteous but almost Chesterfeldian, an old acquaintance has recalled. He never refused a call, gave time, skill and knowledge without thought of financial remuneration, and in addition frequently gave financial aid to the needy. It is remembered that he often said, "It's not so easy for a man to die," and that when death was near in a home in which he was physician, he stayed by to be of aid and comfort to the dying and to the family.

In the early years of scattered communities and few telephones it was common for Dr. Love to be away several days at a time on visits to the sick, for when he reached the home to which he had primarily been called, he would find waiting a neighbor of the patient to summon him to another home miles distant, and so it would continue. Roads of course were poor or nonexistent, and travel in wet weather, through deep clay mud and across open streams, sometimes bridged with structures of uncertain strength, offered many hazards. During the time of spring freshets it was not unusual for both horses and passenger to be obliged to swim to shore; in the winter Dr. Love, like others, often had to extricate his horses from snowdrifts on the roads, shoveling them free and unhitching and leading them out one at a time. When epidemics of pneumonia, scarlet fever, whooping cough and measles, seasonal in the spring, kept the physician almost constantly on the road, the horses suffered; Dr. Love enjoyed and valued fine roadsters and, until the automobile came into use, kept four or five in his stables, so that no one of them should be overworked.

Ethical and loyal to his profession, Dr. Love was no less progressive, keeping in touch with medical advance by periods of study at Rush Medical College, by reading the medical literature and by active membership in medical associations. He is said to have been an early member of the Fillmore County Eclectic Medical Society, which was organized in 1869, the year before he began his medical study with Dr. Ross, and which functioned until 1876. He was elected to membership in the Fillmore (later Fillmore-Houston) County Medical Society, the Southern Minnesota Medical Association, the

Minnesota State Medical Association and the American Medical Association. A general practitioner, he was physician and surgeon and druggist, compounding his own medicines. For more than twenty years, well into the 1900's, he was active in public health work, aiding the State Board of Health and serving on local county and village boards as chairman or as member. In 1886 he was a member, with Dr. J. H. Phillips and Dr. C. H. Robbins, of the newly created medical examining board of the Bureau of Pensions in the county. When the "black diphtheria" broke out, he guarded the community carefully, and to avoid exposing his family to the disease he took living quarters away from his home. In one of his reports to the State Board of Health, in 1886, he stated that the May inspection was preceded by a notice in the newspaper and that "inspection found the town 40 per cent cleaner than last year. . . . A few matters needing attention were promptly attended to. . . . Conditions of county house and jail unsatisfactory. Notice to county commissioners to attend to same." During World War I Dr. Love was medical examiner for the local draft board.

Not a politician, he nevertheless took a keen interest in politics, local, state and federal, and although he inclined strongly toward the Democratic Party, he supported the candidate whom he considered best qualified for office, regardless of affiliation. For several years county chairman of the party, he was instrumental in bringing William Jennings Bryan to Preston during a presidential campaign, to the astonishment of incredulous Preston folk who believed that the great orator would not spend time on a village.

Dr. Love was a member of the Methodist Church of Preston and served as trustee on the church board. Of strong fraternal interest, he was a Mason (a member since December 6, 1876, of the Preston Blue Lodge, A. F. and A. M.; the Preston chapter of Royal Arch Masons; the Malta Commandery, Knights Templar; and the Minneapolis Consistory No. 2, Scottish Rite); a member of the Independent Order of Odd Fellows, and of the Modern Woodmen of America. His library, which was a fine one, was built up chiefly of volumes on medicine, history, travel and biography.

George Allen Love was married on March 5, 1877, to Mary Jane Kingston, who was born at Lenora, Amherst Township, Fillmore County, the daughter of the resident minister, The Reverend William Kingston. Dr. and Mrs. Love had eight children: Claudine died at the age of sixteen from typhoid fever. Bessie became a school teacher who, in the early nineteen-forties, was in Eugene, Oregon. George E. Love, who was graduated from the Medical School of the University of Minnesota, from 1912 was in partnership with his father until the death of the older man in 1930; Dr. G. R̃. Love died in 1941. Frederick Andrew Love, also a graduate of the Medical School of the University of Minnesota, became a practicing physician in Carlos, Minnesota. William was graduated from the Dental School of Northwestern University, Chicago, and practiced dentistry for six years in Preston; during World War I he entered the army, was shellshocked in service and because of the resulting disability has since been a patient in the Veterans Hospital at St. Cloud, Minnesota. Elwyn, also a dentist, a graduate of the Dental College of the University of Minnesota, followed his profession for seventeen years; he subsequently gave up dentistry and became a clerk in the post office at Preston. Helen became a school teacher, employed in the schools of Preston. Maclaren, like his brother William, was graduated from the Dental School of Northwestern University and has practiced dentistry in Preston.

On December 4, 1930, in Preston, Dr. George Allen Love died from a stroke. It is high tribute that his children remember him as a friend and boon companion. No name in the community is recalled with greater respect and honor than his, for his worth as a citizen, his ability as a physician and his kindly, unselfish and unstinted service to the sick.

That **Adolph Mac,** a medical practitioner, had his office on Grove Street, Rushford, in the late sixties is a matter of record, in Mervin's Business Directory for 1869-1870, but other than this brief item information about him is lacking.

Alexander MacDonald, although not a practicing physician in Fillmore County until 1901, when he settled permanently in the community of Chatfield, had been in Minnesota, in Austin, Mower County, and subsequently in Ortonville, Big Stone County, since 1883. Biographical data fortunately have been available and are included here in supplement any accounts of Dr. MacDonald's early professional career in the state that may appear in the narratives from other counties.

Alexander MacDonald was born at Perth, Lanark County, Ontario, Canada, on November 6, 1856, the son of Joseph MacDonald and Margaret MacPherson MacDonald. The parents were natives of Scotland; the father, a farmer, blacksmith and bailiff, was born at Perth, the mother near Sterling. Mr. and Mrs. MacDonald had five children: Jessie (Mrs. Webster), Henry, Margaret, Joseph and Alexander. One of the maternal uncles of these children, the owner of large lumber interests, lived in Ottawa. Their paternal grandfather, a member of a military band, was present at the bombardment of Copenhagen by the British in 1807, and in the War of 1812 he served with the British, it is believed, and after the war remained in America, settling on a tract of government land near Ottawa, Canada.

In Canadian schools and colleges Alexander MacDonald received his formal education, his preliminary and academic training in the grade schools of Paisley, Bruce County, Ontario, and at the Galt Collegiate Institute, at Galt, from which he was graduated in 1877. At Galt the head master was Dr. Tassie, M.A., so well known as a strict disciplinarian that many boys from a distance, even from the United States, were sent to him; cricket and La Crosse were the two games that he considered respectable; baseball and football were "Yankee" and taboo. In the spring of 1877 Alexander MacDonald went to Toronto to take the examination (which he passed) for matriculation in the Medical School of McGill University, at Montreal. During the summers of 1877, 1878, and 1879 he studied medicine under Dr. Peter Maclaren (McGill, 1861) at Paisley, and in 1883 he was graduated from McGill University with the degrees of M.D. and C.M. (Master of Chirurgery). Near the close of his medical course Dr. MacDonald for several months gained valuable experience and credit by substituting in the Montreal General Hospital for an intern who had been taken ill. At McGill he came under the teaching and influence of Dr. William Osler, then a professor of physiology: "The greatest pathologist and diagnostician the world over and still the greatest. Dr. Osler had a magnetic presence and was adored by the whole student body. Under his training I was enabled to have the credit, the honor, of passing the best bedside examination of the year 1883."

In the year of his graduation Dr. MacDonald came to the Middle West and began the practice of medicine in Austin, Mower County. He was then a member of the Medico-Chirurgical Society of Montreal. In that year he served as president of the board of pension examiners of Austin. On January 23, 1884, under the Medical Practice Act of 1883, he was licensed in Minnesota, receiving certificate No. 767; in 1887 he received licenses to practice medicine in Wisconsin and Iowa. In Austin, where by 1885 he had gained a widespread practice, he established a dispensary for the more efficient treatment of his patients. In 1888, in the interest of science, he volunteered to serve the United States Public Health Department in fighting yellow fever but because he was not immune to the disease his offer was not accepted. From 1897 to 1901 Dr. MacDonald practiced medicine in Ortonville, Minnesota, and it was there that he suffered the loss by fire of valuable and irreplaceable records, books, and clinical magazines, as well as his fine surgical instruments and electrical equipment. In Ortonville he served as secretary of the board of examiners of Civil War pensioners.

On September 30, 1890, Alexander MacDonald was married to Margaret Anna Forster, a school teacher in the community of Chatfield, who was born on January 8, 1861, of English parents, on a farm in Orion Township, Olmsted County, near Chatfield. Dr. and Mrs. MacDonald had one son, an only child, William Joseph Alexander MacDonald, born in 1893, whose life was a credit to his home and his country. Student and athlete, he was a graduate from the Law School of the University of Washington, at Seattle; in 1917 he was captain of the university track team and competed in the mile and the two mile runs. In World War I he entered the army and soon became a first lieutenant in the Rainbow Division; when he was at corps school in France, he received highest standing in tactics and was recommended for a majority. On the morning of October 14, 1918, Lieutenant MacDonald was killed in action in the Argonne. He was awarded the Distinguished Service Cross; and MacDonald Field, of the University of Washington, was named for him "for all time."

During World War I Dr. MacDonald offered his services to the army but because he was past the age limit his offer was refused. He is a Presbyterian and a member of the Independent Order of Odd Fellows, and has served as a medical examiner for the Modern Woodmen of America. He has said of himself that as a business man he was a "poor collector;" his sympathies were always with the tellers of hard luck stories.

During the years of his active and heavy practice, although Dr. MacDonald did not identify himself with medical associations, he kept abreast of medical advance by study and by reading the medical literature, a habit which he continues. He has had especial interest and pleasure in the reading of history, the classics and the works of Dickens, Thackeray and Scott and, well versed in French, for many years he read a daily French newspaper. One of his hobbies, which developed during his recuperation after an illness, has been searching locally for ginseng.

For many years after he settled in Chatfield, in 1901, a promising location and near Mrs. MacDonald's relatives, he maintained his office in his home. Of late years, because of ill health, he has not followed his profession and has lived in retirement in a comfortable home in the country near Chatfield. Mrs. MacDonald died suddenly at home from a stroke on August 29, 1943. She was survived by her husband and by one sister, Mrs. H. P. Foote, of Saint Paul.

(To be continued in the May issue)

President's Letter

MEDICAL BENEVOLENCE

The yearning of nearly every human being to care for something other than himself is one of the most praiseworthy traits of man. Strangely, this characteristic is found not only among the good and virtuous but it has been manifest in many who were evil or even depraved. In a free society, then, these may be taken as universal principles: that sympathy is excited by suffering; that cruelty is counteracted by benevolence; that new evils are met by new remedies; and that the injustice of some provokes the charity of others.

Thus it is that, even at a time when the energies of all members of our association are so greatly needed in the attempt to care for the sick, and despite the confusing and obstructive organizational tasks which demand our attention nearly every day, the better side of our nature asserts itself and we find time to reflect concerning the condition of colleagues who are less fortunate than we with respect to possession of this world's goods. We realize that some members of our profession have reached the age of retirement practically destitute. We know that some younger practitioners who have been incapacitated by early illness have found themselves and their wives and children without means of support. We are familiar with the sad plight of some widows of physicians. Our awareness of these calamitous situations, I believe, will impel us to try to mitigate them.

Already, physicians of Illinois, of Pennsylvania and probably of other states have come to grips with this problem. Several years ago the House of Delegates of one state medical association created a Committee on Medical Benevolence. Among other duties, this committee searches for members of the medical profession who are in poor health and who need financial assistance. Also, the committee is instructed to search for widows of former members of the society or their dependent children who need aid. The committee decides as to the eligibility of prospects who are discovered and as to the amount of money which is to be provided. The records are subject to annual audit but names of beneficiaries do not appear on the auditor's report and no one other than members of the committee and the auditor knows who the beneficiaries are.

One of the programs just described was begun with an appropriation of $5,000 from the treasury of the state medical association. Since then other appropriations have been added. At one time a drive was made among the members of the association for money to augment the permanent fund. The response to this request was unbelievably gratifying. There are other sources of funds. For example, a number of elderly patients of members of the association have added codicils to their wills by which they have left money to the fund. Other philanthropic individuals also have made contributions.

Interesting problems have developed as a result of such efforts. For instance, the widow of a prominent surgeon found herself almost destitute after all expenses had been paid following the sudden death of her husband. Her name was added to the list of beneficiaries of the state medical association. In another case, a young physician, with two children, contracted tuberculosis. He was confined to a sanatorium for eight months. All his expenses were met by the medical benevolence fund. The beneficiary's name was never divulged. An aged physician, after his retirement, had set up a new residence in Florida but had failed to leave his new address with his state association. Nevertheless, he was discovered in his new home when, after ten years there, he became ill and needed assistance. His problems were solved by the contributions from the fund and his economic safety was assured until his death. Many stories of this kind could be related.

The development of a medical benevolence project in our state organization, and perhaps also in the American Medical Association, is something I would like to witness and in which I would like to participate. To care for our own quietly, seems particularly appropriate in an essentially humanitarian organization such as ours; especially so when we consider that of a number of those who will need our care it can be said: "These were honored in their generations, and were the glory of their times."*

Louis A Buie

President, Minnesota State Medical Association

MINNESOTA CANCER SOCIETY

THE Minnesota Cancer Society, along with the American Cancer Society, of which it is a component part, has shown a phenomenal increase in membership and activity in recent years. The American Cancer Society, originally known as the American Society for the Control of Cancer, languished for a number of years, until businessmen began to lend their services, and the Women's Field Army was organized to participate in the raising of funds. In 1940 the national fund-raising campaign netted about $400,000; this year it is anticipated that the amount raised will reach $16,000,000. In Minnesota alone, over $228,000 was contributed last year by more than 43,000 individuals and 4,000 corporations. Forty per cent of Minnesota's yearly contribution, earmarked for research, goes to the national organization and is apportioned to various university medical schools.

The objectives of the American Cancer Society are (1) research into the causes of cancer, (2) education of the public and the medical profession, and (3) provision of medical care for needy cancer sufferers with emphasis on these activities being placed in the order mentioned.

For a number of years another organization, the National Cancer Foundation, incorporated originally as the National Foundation for the Care of Advanced Cancer Patients, has been raising funds on a national basis for the care of incurables. This organization has apparently felt that more emphasis should be placed on this objective. It is unfortunate that this organization, with a most worthy objective, should have changed its name to the National Cancer Foundation, a name so similar to the American Cancer Society as to confuse the public. The designation of March each year for a Foundation fund-raising campaign, just preceding the April campaign of the American Cancer Society, is still further confusing to the public. One national cancer organization should be sufficient. It might be noted that the National Cancer Foundation has not received the approval of the Minnesota Community Research Council, a state-wide committee established since the war to provide reliable information on organizations soliciting funds.

After due deliberation, the Executive Committee of the Minnesota Cancer Society decided that the greatest need at present in the cancer problem in Minnesota is the provision of suitable quarters for research at the University. Minnesota was one of the first universities to establish a cancer research department, but at present it has a crying need for expanded facilities. The society therefore presented a check for $75,000 for this purpose to Dr. H. S. Diehl, dean of medical sciences of the University Medical School, at its annual meeting on March 8, 1947. Dr. Diehl, in accepting the gift for the University, indicated that the donation would doubtless be used to help defray the cost of providing suitable quarters for cancer research in the new Mayo Memorial building.

Someday the cause of cancer will be found. At present, $5,000,000 ($1,500,000 appropriated by the Federal government and $3,500,000 by the American Cancer Society) are devoted to cancer research. When we consider the governmental appropriations for research in various other lines—two billions in the development of the atomic bomb, for instance—the amount devoted to cancer research does not seem adequate for a disease which during the war period caused twice as many deaths in our country as the war itself. We do not necessarily advocate increased Federal subsidies for cancer research. Increased contributions to the American Cancer Society should provide sufficient funds to carry on the needed research, with the assurance that the ultimate goal will someday be reached.

FADING INK

THE use of ink which does not fade and which is photogenic—that is, which is reproduced clearly in photostatic copies for all records where permanency is essential—is not a new subject. Insurance companies and departments of vital statistics have insisted for years on the use of black or blue-black ink in the filling out of application blanks or certificates. Such records are of a permanent nature and are photographed, in the case of birth and death records, sometimes years later.

The popularity of so-called ball-point pens equipped with long-lasting cartridges has brought to the fore the subject of the use of non-fading ink, which produces a smooth dark line, for important documents. Ball-point pens are manufactured by a number of firms. The inks in several brands of these pens were tested about a year ago by the National Bureau of Standards, and all were found to fade quickly. Some manufacturers have been attempting to improve the ink used in these pens by adding compounds which are known to be light resistant. Tests have shown that writings made with these modified products have been found to leave a readable residue after exposure to a period of radiation equivalent to 100 hours of June sunlight. However, these improved inks are by no means in all pens.

The use of non-fading ink for physicians' records is of considerable importance. It was considered of sufficient importance by one clinic in Minnesota to justify the manufacture of its own ink for the past twenty years and the insistence on its use by all members of the group.

At the request of the Division of Vital Statistics of the Minnesota State Department of Health, the attention of the profession is called to the obvious importance of the use of non-fading, black or blue-black ink in filling out birth and death certificates.

TUBERCULOSIS SURVEYS IN MINNESOTA

In mass surveys for cases of hidden tuberculosis, the use of the 70 millimeter photofluorographic unit affords a distinct advantage over the usual method of Mantoux testing followed by examination of positive reactors on a 14 by 17-inch x-ray film. While the initial cost of a photofluorographic outfit is considerable, the overall cost in mass surveys is said to amount to about 35 cents per individual.

The detection of pulmonary tuberculosis by means of the 70 millimeter film has proved sufficiently accurate to warrant its use. Some practice is required to determine which individuals require a retake on a large film. Those individuals who show the usual involvement characteristic of pulmonary tuberculosis are referred to their family physician for determination of the presence of an active lung lesion. Although the x-ray is only a record of shadows, it is admittedly the most valuable single diagnostic aid in pulmonary tuberculosis. The referring of the individual back to his family physician places the responsibility of determining the need for treatment directly in his hands. It is to be hoped that the physicians of the state, cognizant of the importance of x-ray findings, will co-operate in every way in the mass surveys being made and about to be made.

The Ramsey County Public Health Association has purchased a 70 millimeter x-ray unit and, in co-operation with the Saint Paul Health Department, has examined several thousand individuals in the health department quarters of the Court House. Each roll of film provides for 350 exposures, and the ease with which this number of pictures can be taken in a day is impressive.

In April this unit will make a survey in North Saint Paul and then return to another section of Saint Paul.

In May a unit provided by the United States Public Health Service, in co-operation with the Hennepin County Tuberculosis Association and the Minneapolis Health Department, will attempt to x-ray the entire population of Minneapolis. This is the first time the attempt will have been made to cover a large city. Success will depend on the co-operation of all its citizens. It is a foregone conclusion that a certain number of unrecognized cases of pulmonary tuberculosis, as well as some instances of other abnormal chest conditions, will be unearthed. If the Minneapolis survey runs smoothly, doubtless the procedure will be carried out in other large cities.

One word of warning should perhaps be offered to the profession. Many cases of healed pulmonary tuberculosis will be revealed. These individuals should be accurately classified and not subjected to active treatment.

The 16,000,000 hospital admissions and the undetermined additional millions of people seen in outpatient departments yearly provide a fertile field for x-ray detection of tuberculosis. A few hospitals x-ray each patient admitted, as well as all hospital employes. The incidence of tuberculosis in this group is naturally high, and its detection is beneficial not only to the affected patient but as a protection to other patients and hospital personnel. According to *Tuberculosis Abstracts* for April, 1947, the United States Public Health Service is about to approve funds for the placement of several hundred photofluorographic units in hospitals unable to provide them for themselves.

INTRAVENOUS ETHER—AN AID TO COLLATERAL CIRCULATION

IN his discussion of Dr. Joseph Borg's thesis on "Peripheral Arterial Embolism," presented before the Minnesota Academy of Medicine and appearing in this issue of MINNESOTA MEDICINE, Dr. Moses Barron described his experience in the use of ether intravenously in a patient suffering from arterial embolism—a procedure called to his attention in Toronto.

Our attention has been drawn to an article by Katz[†] in which he described the development of his present technique in the use of ether intravenously in the treatment of ischemia of the extremities due to diabetic and senile arteriosclerosis, Buerger's disease and Raynaud's disease. Using himself as a guinea pig, Katz promptly found that intramuscular injections of ether alone or in peanut oil were very painful. The addition of benzocaine made the injections less painful but, even with the addition of penicillin, six of thirty-four patients so treated developed deep ulcers. The result, however, of intramuscular injection of this mixture of ether, peanut oil, benzocaine and penicillin, proved the marked beneficial effect of ether in these patients and led him to try the administration of ether intravenously. The safety of this method had long ago been established in producing anesthesia. He began with 10 c.c. of ether in 90 c.c. of either normal saline, 1/6 molar lactate solution, or 5 per cent dextrose in distilled water, given very slowly. A stinging sensation and the production of thrombosed veins at the site of the injection soon led him to dilute the solution to 10 c.c. of ether in 190 c.c. of diluent. In his last twenty-two patients he diluted the ether still further, giving 25 c.c. in 1,000 c.c. of diluent daily.

In his reported series of sixty-six cases treated intravenously, good results were obtained in fifty-eight. Relief of pain and improvement in circulation were outstanding. No deleterious side effects on the blood, kidneys or other tissues were noted.

How the beneficial effect of ether is produced in these patients suffering from local ischemia from one cause or another, is not known. Presumably the ether increases the collateral circulation in the affected limb. The inefficacy of remedies so far proposed for the alleviating of the suffering of these unfortunate individuals makes the trial of an apparently effective remedy well worth while.

BRONCHIAL ASTHMA

(Continued from Page 393)

a special problem, and predisposing causes for the development of overt asthma should be controlled. If this is done wisely, there need be no inferior complex.

In conclusion, let us all recognize the handicaps and hazards which all potentially allergic individuals must encounter and not permit them to become asthmatic. Let us study each individual asthmatic with the intention of keeping his threshhold of immunity to allergins high so that his occasional paroxysms may not become frequent or chronic, and so no one may reach the status asthmaticus or suffer from often long-delayed, serious pathological consequences of the malady.

REPORT OF THE HOUSE OF DELEGATES—AMERICAN MEDICAL ASSOCIATION

December 9-11, 1946

There are several features about the December meeting of the House of Delegates of enough importance to warrant reporting to the members of the Minnesota State Medical Association.

First, is the question of the Rich report. A year ago, the Board of Trustees of the American Medical Association recommended that there be a complete survey made of the workings of the Association. They employed a firm called the Rich Associates to make a thorough examination into American Medical Association affairs. As a result of this investigation, the organization of the Association is now divided up into different divisions.

One is the editorial division, which is under the supervision of Dr. Morris Fishbein, who is editor of *The Journal of the American Medical Association* and *Hygeia* and has charge of all other publications of the Association.

Another division is devoted to public relations, which is to be under the guidance and direction of the General Manager of the Association. The duty of this division will be exactly what its title implies—Public Relations. The department has now been set up and is in operation; already it is showing good results.

A third division is concerned with medical economics. Much attention has centered lately on legislation for compulsory health insurance, regimentation of medicine, et cetera, which has been recently introduced not only in the national Congress but in state legislatures as well. To study matters of this kind is the purpose of the medical economic division. Posts in this division have all been filled by competent men chosen by the Trustees of the American Medical Association.

Generally speaking, there were many more matters, of no particular consequence, that needed to be checked and which could be corrected. Most of these suggestions for improving the Association's internal workings were accepted with good grace by the Delegates.

The entire Rich report, with one exception, was very instructive and for the good of the AMA. The one exception was the question of the alliance between the American Medical Association and the National Physicians Association. This report was not favorable. However, further questioning of Mr. Rich revealed that this was not based on a thorough enough investigation of the National Physicians Association. Mr. Rich promises to continue the investigation until June, at which time he plans to bring in a much more exhaustive report. The House of Delegates is looking forward to hearing more about this at the annual meeting in Atlantic City.

A second item taken up by the delegates which warrants attention is the question of the revision of the Constitution and By-Laws of the American Medical Association. What was presented in this connection was, in reality, not a new constitution and by-laws but rather a correlation of many proposed changes, passed upon previously and admitted as amendments, but never brought together in a concise form. The job of correlating all of these amendments represents a lot of hard work on the part of the committee.

The third matter on the program was a discussion of the progress in the field of prepayment medical service. From the discussions it was apparent that the American Medical Association has a well-rounded program, which provides for co-ordination of efforts at the state as well as the national level.

The next important item was probably the report by Dr. Boone, Rear Admiral in the Navy, on the conditions in coal mining districts. He reported on housing conditions and medical problems; and from his report it was learned that health and sanitary conditions are deplorable in some areas. It is hoped that miners, unions and mine operators can get together on a program which will provide better housing, better living condtitions and better medical care. For this particular purpose a certain amount is to be deducted from the price of each ton of coal mined; this amount is to be turned over to the Union. The method by which the Union shall handle this money is yet to be determined, and it was agreed by the House of Delegates that the medical profession "should play a leading role in the evolution of these plans for medical care" and should assume leadership in the formulation and establishment of reasonable and practical programs that will benefit the people. Developments in this field will bear watching by every physician. (For more details on Rear Admiral Boone's report, see MINNESOTA MEDICINE, February, 1947, Pages 190-192.)

Another important item is the present plans that are being made for a very elaborate Centennial Celebration in Atlantic City in June, which will feature a great many distinguished speakers from this country and from foreign countries.

An important discussion was held on the question of rural medical care, which seems to be a number one problem in the practice of medicine in the United States at the present time. A broad program was outlined calling for better qualified doctors in rural districts, better distribution of health centers and more nurses.

Delegates heard an interesting report from Dr. A. C. Ivy of Chicago, who was delegated by President Truman to investigate Nazi medical experiments made during the war. As a result of hearing about these experiments, certain principles to be followed in making experiments using human beings as subjects were agreed upon by the delegates. (1) Voluntary consent of the individual upon whom the experiment is to be made must be obtained before proceeding with the experiment. (2) The danger in each experiment must be thoroughly investigated previously by animal experimentation. (3) The experiment must be performed under proper medical protection and management. These general principles were accepted by the delegates; apparently none of them were followed in the Nazi human experimentation program.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

COUNTY OFFICERS HEAR PROGRESS REPORTS ON MSMA PROGRAMS

Recent accomplishments of the medical profession in Minnesota, as well as medical economic problems still facing state doctors, were reviewed when the officers of local medical societies composing the Minnesota State Medical Association gathered in Saint Paul March 1 for their annual County Officers meeting.

That rapid strides have been made by the profession in at least two fields—prepayment medical service and veterans' medical care—was apparent in the progress reports of those two programs, which during the past year have materialized from mere plans into actual organizations.

Operation of the new Veterans Medical Service division, which began functioning February 10, were described. Dr. Richard B. Hullsiek, Minneapolis, Chief Medical Officer of the Regional office of the Veterans Administration, told the delegates about the VA program and how the Veterans Medical Service division fits into the government setup. Mr. Philip J. Lemm, who has been directing the work of the new division, gave the doctors a general, over-all picture of how it operates.

Veterans Number About 400,000

Dr. Hullsiek estimated that the veterans in the state, eligible for benefits at federal expense, number between three and four hundred thousand. Included in these benefits, he said, are rehabilitation, educational training, pensions, insurance and medical service.

The work of the Veterans Medical Service division has been complicated, Dr. Hullsiek pointed out, by the slowness of the Washington VA office to approve Part II of the fee schedule developed by the State Association Veterans committee.

Part I, appended to the contract executed between the VA and the MSMA—containing as it does only some forty-eight items—barely scratches the surface of services that doctors will find it necessary to perform. This means, Dr. Hullsiek said, that the twenty-five-year-old VA fee schedule must still operate for the bulk of the services rendered by the doctors. However, all possible pressure is being exerted on the Washington office to remedy this situation, and pending approval of Part II in its entirety, assurance has been given that some fifty or sixty items under Part II, selected by the Regional Office for their frequency in authorization requests, would be appended to the contract immediately, Dr. Hullsiek said. It is hoped to have ninety-five per cent of the veterans medical service handled through the State Association VMS division in a very short time.

Prepayment Medical Service Program

Dr. O. I. Sohlberg, president of the Minnesota Medical Service, Inc., the prepayment plan approved by the House of Delegates last December to co-ordinate its services with the Minnesota Hospital Service Association, reported to the county officers that the board of directors was working hard to secure an executive director and to put the corporation on a functioning basis. Minnesota Hospital Service has been more than co-operative, Dr. Sohlberg said, and it will be just a matter of weeks before Minnesota Medical Service will be ready to start operations. Literature explaining its services in detail will be available soon.

Another report heard by the county officers dealt with conferences between the MSMA and the Insurance Liaison committees which are setting up a program that will serve as a second arm to broaden the base for prepayment medical insurance coverage in Minnesota.

Co-operation with Insurance Companies

Dr. B. J. Branton, co-chairman of the five-member MSMA liaison group, appointed by the

Council at the direction of the House of Delegates in December, explained the objectives of the Conference Liaison committee in this way:

> "Co-operation of medical groups with insurance companies is a normal procedure if for no other reason than the fact that up to now no better way has been found to eliminate the financial barrier between the patient and the doctor and the patient and the hospital than through recognized insurance companies providing the indemnity on a guaranteed cost basis.
>
> "Financial barriers, not the doctors, are the cause of inadequate medical care which low income groups receive under existing conditions," Dr. Branton declared, "and providing adequate medical care by eliminating these financial barriers stretches into the fields of economics, education, human relations, government and even politics, unfortunately."
>
> "The Liaison committee," Dr. Branton want on, "is only a part of the national setup developed by the Council on Medical Service of the AMA, and it will work wholeheartedly with the Council as it co-ordinates its activities with those of insurance companies."

Liaison Committee to Set Minimum Standards

Minimum standards will be agreed upon soon by the Conference Liaison committee, Dr. Branton announced, and the companies in the state, which after careful scrutiny meet the approval of the State Insurance Commissioner and the MSMA committee, will be given opportunity to apply for approval of the AMA. In this way Dr. Branton explained, there will be a double check—locally and nationally—before approval is granted in the state.

While medical service contracts are now being written by companies individually at an accelerated rate, under the stimulus of activities by the state medical association, it is felt that the medical profession's approval of contracts that meet minimum standards will greatly benefit the public in the protection and security afforded under these contracts, Dr. Branton said.

Rural Health a "Perennial Issue"

Rural health, which has been converted into a "perennial issue" by the Michael Davises and Senator Murrays in their carefully conceived plans to foster government medicine in this country, was discussed with all its ramifications by Dr. L. W. Larson of Bismarck, area chairman of the AMA committee on Rural Medical Service. Said Dr. Larson:

> "Medical care is only a part of the problem of rural health. Good housing, adequate and balanced diets, health education, sanitation, immunization against communicable diseases, hygiene, dental care and instruction for expectant mothers and infant care, are of equal importance."

Expanded public health activities through the development of full-time county or regional health units will solve much of these extra-medical components of the rural health problem, according to Dr. Larson.

> "Let us recognize," Dr. Larson urged, "that there are problems involved in rural health, and that, as physicians, we have a responsibility to help correct them through a constant effort to raise medical standards and to develop a spirit of co-operation with any and all people who are honestly concerned with the welfare of our rural population."

Lay Speakers at Rural Health Conference

As an expression of their appraisal of current medical care in rural areas, Dr. Larson quoted two lay speakers at the Second Annual Conference on Rural Health, held in Chicago in February. To quote Albert S. Goss, Master of the National Grange:

> ". . . Thus we see that the high cost of adequate medical care relative to farm income and the lack of modern medical facilities in rural areas adds up to a real problem. When we add to this problem the abuses of overcharge and unethical practices that some doctors are guilty of, and which most of us have been the victims of, it adds up to an overwhelming demand for better medical service."

In what amounts to a blunt indictment of medicine that could scarcely be considered a true picture of conditions as they are known to exist generally, Mr. Goss has charged, Dr. Larson said, that "the feeling has become more and more general that the medical associations, instead of devoting their chief efforts to the improvement of medical standards, have been more interested in eliminating competition in the medical field!" Mr. Goss, as quoted by Dr. Larson, maintains that this is the reason that medical service is "not only much more costly, but much more difficult to secure." Mr. Goss has further said that rural America is "up in arms" over the inadequacy of medical service resulting from this attempt by medical associations to monopolize the field.

Mr. Mertz Takes Milder Approach

Reporting further on the Chicago Conference, Dr. Larson quoted from the somewhat milder remarks of Edward H. Mertz, administrative assistant in the Department of Education of the National Farmers Union, who spoke of deficiencies in a more conciliatory vein. Mr. Mertz, Dr. Larson said, cited the following wants and needs of rural people in the way of medical and health services:

1. More doctors, dentists and nurses *closer to them*
2. More hospitals and clinics in their communities
3. Better housing and sanitary facilities
4. Sufficient income to absorb their costs

From the statements of these two men, Dr. Larson said, it may be concluded that rural people believe that there are not enough doctors and hospitals in rural areas, and that medical care is too expensive.

"Medicine Has Outgrown Horse and Buggy Days"

Looking at the contributing causes for this lack in health facilities, Dr. Larson maintained that the reasons for the lack are fairly obvious to the medical profession. To quote him:

> "Medicine has outgrown the horse and buggy days just as agriculture has. Farmers think nothing of driving 25 to 50 miles to do their shopping. In fact, many farmers consult the doctor in that trading center during the same marketing or shopping trip. In so doing they by-pass the physician in the small town en route—that is, if there is one left. Why? Because the practice of medicine has changed from the horse and buggy days when the doctor could carry his entire diagnostic and therapeutic armamentarium in one bag. Today he needs special equipment and diagnostic aids, both technical and professional, which he cannot possibly bring to the patient. The obvious answer is to bring the patient to the doctor."

While the profession itself is doing everything it possibly can to induce more doctors to locate in rural areas, Dr. Larson said, it realizes that a complete medical and hospital service cannot be developed at every crossroads, but that such service can be developed in the larger communities which are the trading centers. In order that the wave of emotional enthusiasm for the construction of a hospital in almost every small town and city will be guided in the right direction, the AMA and every state medical association is co-operating in an advisory capacity with lay committees throughout the country.

Many of the shortcomings charged to the medical profession are due to the lack of aggressive leadership in health education by local doctors. To overcome this difficulty, Dr. Larson said, state medical associations, as well as county medical societies, must become inculcated with a spirit of public welfare and leadership in worthwhile health movements.

A second, final installment of the review of the discussions held at the 1947 County Officers Meeting will appear in this column in the next issue of Minnesota Medicine.

Minnesota Academy of Medicine

Meeting of December 11, 1946

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club, on Wednesday evening, December 11, 1946. Dinner was served at 7 o'clock and the meeting was called to order at 8:10 by the president, Dr. S. E. Sweitzer.

There were fifty members and one guest present.

Minutes of the November meeting were read and approved.

In regard to attendance at meetings, Dr. Hall made a motion that a letter be written to those who had not attended the required number of meetings during the year, calling their attention to the ruling in the Constitution regarding attendance. Motion was seconded and carried.

The annual election of officers resulted in the following being elected for the year 1947:

President..............Dr. E. M. Hammes, Saint Paul
Vice President........Dr. T. A. Peppard, Minneapolis
Secretary-treasurer........Dr. A. E. Cardle (re-elected)

The scientific program followed.

Dr. L. R. Boies, Minneapolis, read his Inaugural Thesis.

MENIERE'S DISEASE: ENDOLYMPHATIC HYDROPS

LAWRENCE R. BOIES, M.D.
Minneapolis, Minnesota

Although Ménière described a condition characterized by the symptoms of vertigo, deafness and tinnitus in 1861, it has only been within the past ten years that pathologic changes within the inner ear have been described to account for these symptoms.

We have in our literature concerning this symptomatology a confusion of terms. "Ménière's syndrome," or "Ménière's symptom complex" and the term "pseudo-Ménière's disease" in cases of vertigo without auditory symptoms or neurologic signs, are all commonly used. There are several conditions which can produce this triad of symptoms, among which there now seems to be a clear-cut clinical entity in the nature of a labyrinthine hydrops. The evidence for this has been obtained from a microscopic study of temporal bones from persons who were known in life to have experienced severe and repeated attacks of vertigo accompanied by hearing loss and tinnitus, without any other morbidity to associate with the causation of these symptoms.

Some of the references in the literature to Ménière's papers have indicated that his original description was concerned with a case of labyrinthitis. In a search for Ménière's account of his "classic case," McKenzie[9] failed to find an adequate description to fit our present conception of the clinical characteristics of the disease which bears Ménière's name. However, Simonton[13] in an exhaustive review of the literature in 1940 refers to six articles published in 1861 by Ménière, most of them in the *Gazette Medicale de Paris.* He personally translated these papers. I am indebted to him for a copy of the pertinent portions of these translations which show that Ménière did describe with clarity the symptomatology as we know it today.

The first microscopic observations on the temporal bones of persons known to have had severe attacks of vertigo, deafness, and tinnitus during life were described in 1938 by Hallpike and Cairns.[7] Lindsay[8] corroborated their findings in 1942. To date, histopathologic findings on twenty-one temporal bones from seventeen cases have been reported. The pathologic findings indicate a labyrinthine hydrops, from which it seems reasonable to conclude that it is the effects of this hydrops which produces the morbidity. To date, however, we have no definite evidence of the *etiology* of the hydrops.

The most constant histopathologic finding is a dilatation of the cochlear duct (Fig. 1). In some cases, dilatation had occurred in the saccule, the utricle, or the ductus reuniens. Other changes of a degenerative nature were noted in the maculae or cristae. A localized labyrinthitis occificans was also noted.

Before Hallpike and Cairns made their observations, Mygind and Dederding[10] in 1932 had advanced the hypothesis that the symptoms of Ménière's disease are due to a "waterlogging" of the labyrinth. This inspired certain chemical investigatons which have not established definite etiologic factors but have resulted in medical therapeutic measures which though empirical are widely used today. Furstenberg and his co-workers[5,6] in 1934 reported observations from which they concluded that the tissues responsible for Ménière's disease were sensitized to the sodium ion, and that if retention of sodium is prevented and its elimination promoted, patients suffering from the disease may be relieved. Shelden and Horton[12] in 1940 reported observations on the use of histamine to relieve the symptoms of Ménière's disease. These investigators expressed the belief that the factor most likely to be responsible for Ménière's disease is an alteration in the permeability of the capillary walls with secondary edema of the middle ear, and that histamine is an important agent in affecting capillary permeability. Williams[16] regards the symptoms of Ménière's disease as a manifestation of an intrinsic physical allergy which in his experience may respond to treatment with nicotinic acid.

Clinical Manifestations

Symptoms.—In a typical case of Ménière's disease, the patient complains of vertigo, tinnitus, and deafness.

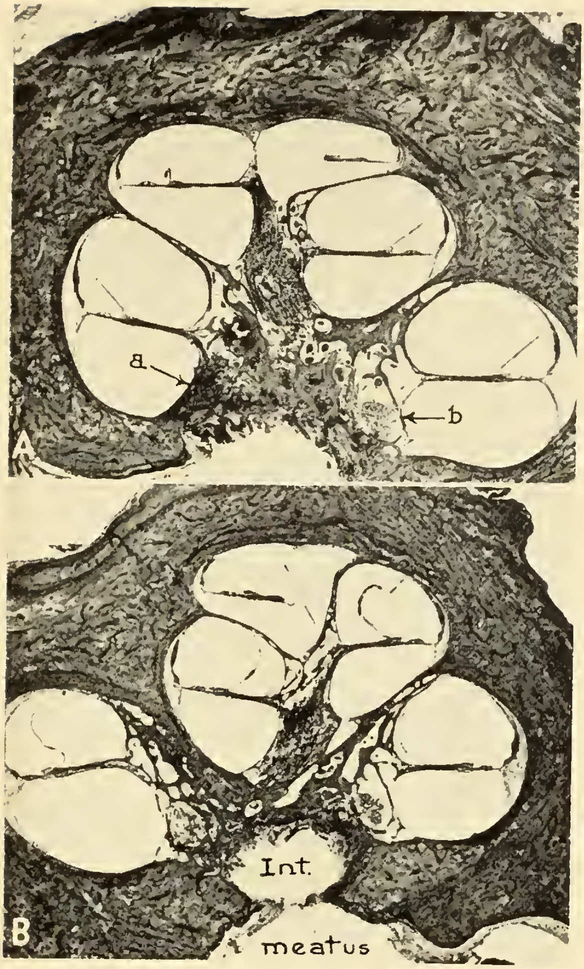

Fig. 1. Section from the temporal bones of a forty-seven-year-old man who fell during an attack of vertigo, suffered a fracture of the skull and died from a subdural hematoma. He had been examined in 1939 at the Mayo Clinic, where a diagnosis of Ménière's disease was made. He was reported to have had normal hearing through the speech frequencies in his right ear. In the left, there was a loss of 30 decibels for low tones, including the 2048 cycles. A cold caloric test showed a diminished response on the left side. The results of his general physical and neurologic examinations were normal.

(The temporal bones were sent to Dr. John R. Lindsay of the University of Chicago, who supplied the author with serial sections of these bones, one of which is pictured here. Dr. Lindsay has reported this case in detail: Ménière's disease. Arch. Otolaryng., 39:313, 1944.)

A is a horizontal midmodiolar section through the right cochlea. The ductus cochlearis is normal. The loss of Reissner's membrane in the upper coil is an artifact. The vessels are congested, and extravasated red blood cells are present in the internal meatus and the lamina cribosa and are invading the spiral ganglion (a). The spiral ganglion of the basal coil shows degeneration (b).

B is a vertical midmodiolar section of the left cochlea. The ductus cochlearis is greatly dilated and herniating through the helicotrema. The blood vessels are congested, and some extravasated blood is present in the internal meatus. The spiral ganglion shows degenerative changes in the basal coil.

The vertigo is the most disturbing symptom and may overshadow the other two. As a rule, it occurs suddenly, without warning, and may occur while the victim is at rest, even during sleep. A history is not infrequently given of the occurrence of an attack as the patient turns over in bed, or on awakening, or on getting out of bed. The duration of the vertigo may vary from a few minutes to a few days, or in a subacute form for weeks or months. In the majority of cases, the patient describes his vertigo as rotatory, in which he feels that objects about him are whirling or that he is whirling. However, a labyrinthine disturbance can occur in which the whirling sensation is absent but in which the patient experiences a swaying sensation or a sense of weakness or movement in which there is actually no sense of rotation.

The deafness in Ménière's disease usually is of the nerve type affecting the high tones first and may be severe. It tends to fluctuate but may be progressive, confined to one ear, or affect both ears in different degrees. The degree of deafness is not diagnostic.

Tinnitus is the most variable symptom of the triad. Its cause has not been established. If both ears are involved, the tinnitus is usually present in the more involved of the two ears.

Diagnosis.—Inasmuch as two of the symptoms, the vertigo and tinnitus, are subjective, the patient's descriptions of his symptoms are very important.

The caloric test will as a rule reproduce the vertigo that the patient describes. The results of this test are not, however, diagnostic of Ménière's disease. Crowe[2] has reported a series of cases in which the caloric test was normal in 35 per cent, subnormal in 19 per cent, and that in 29 per cent the labyrinth of the affected side failed to react (17 per cent were not tested).

In considering a diagnosis of Ménière's disease, it is important to exclude chronic middle ear disease, lesions of the central nervous system, cardiovascular disorders, et cetera, as a cause of vertigo.

Treatment.—Two forms of treatment are in current use. The medical treatment should be tried in all cases first; surgical therapy should be reserved for severe cases which do not respond to medical treatment. The efficacy of all treatment should be considered in light of the fact that long remissions in the symptoms may occur in this condition. Mild cases are helped by the use of sedatives.

The sodium-free diet of Furstenberg, Lashmet, and Lathrop has been referred to previously in this paper. They recommend a special diet avoiding salt and low in sodium. Ammonium chloride, an acid-producing salt, is administered in six 7½ grain capsules three times daily during meals. This drug is taken for three days and then omitted for two days. The treatment is continued for several weeks and is gradually discontinued according to the patient's condition.

Desensitization to histamine was recommended by Shelden and Horton[12] during the acute stage of Ménière's disease. They used a dosage of 1.9 milligrams of histamine acid phosphate dissolved in 250 cubic centimeters of normal physiologic salt solution and administered intravenously in approximately an hour and a half. The treatment was repeated on two or three successive days. There have been some modifications of this dosage.

Dr. A. B. Baker, who has had an extensive experience with histamine therapy at the University Hospital in Minneapolis, now uses the following method: 2.75 milligrams of histamine acid phosphate in 250 cubic centimeters of normal saline are given intravenously to outpatients daily for fourteen consecutive days. The administration is given right after a full meal. About two and a half to three hours are taken for each treatment. A glass or two of milk is given by mouth during the treatment. Four additional treatments on alternate days are then given so that the full course takes a total of eighteen treatments. The patient is then put on 50 milligrams of benadryl twice daily for six weeks.

Talbott and Brown[15] have reported success in the control of Ménière's disease by the adminstration of a potassium salt with the patient on a normal diet.

If medical treatment fails to control the vertiginous attacks of Ménière's disease, the patient then has recourse to more certain benefits from surgical therapy. This is particularly true if the disease is unilateral as evident from symptoms and signs referable to one ear only. Five different surgical procedures have been described. Dandy[3] was an exponent of nerve section. Portmann[11] described a destructive operation on the saccus endolymphaticus. Wright[17] has had considerable success with the injection of alcohol into the labyrinth by way of the oval window. Cawthorne[1] has reported a large series of cases with a high percentage of successful results by performing a labyrinthotomy and excising a piece of the membranous labyrinth. Day[4] has advocated opening the external semicircular canal anl coagulating the membranous labyrinth with a weak diathermy current (Fig. 2). It is a relatively simple procedure in which there is the possibility of preserving some of the residual hearing. Sullivan[14] has recently been able to accomplish this by a limited coagulation of the vestibular portion of the labyrinth, carrying out this part under the magnification of a dissecting microscope.

Because of the relative simplicity of Day's procedure with a possibility of preservation of residual hearing function, this operation seems destined to be generally adopted. In the past two years, I have performed this operation on five cases. Brief case histories of these patients follow:

Case Reports

Case 1.—R. J., a thirty-nine-year-old public health nurse, was first examined on August 21, 1943. She gave a history of having had recurrent attacks of vertigo for ten years with some loss of hearing and a low-pitched tinnitus in her left ear. She had been treated after the method of Furstenberg and his co-workers and had had a trial of histamine desensitization. A neurosurgeon had recommended nerve section.

Hearing tests revealed a normal response in the right ear and a marked depression in the left ear, approximately the 70 decibel line through each frequency except for the 2048, which was at the 40 decibel line.

A labyrinthotomy on the left ear was recommended. The patient decided to consider this procedure and meanwhile to try nicotinic acid therapy.

The patient was next examined on August 31, 1944, by which time she had decided to undergo surgery because the attacks were incapacitating her. Caloric tests were performed after the method of Kobrak. The reactions were within normal limits on each side.

A labyrinthotomy on the left ear with coagulation of the membranous labyrinth after the method of Day was performed on September 11, 1944. Convalescence was uneventful except for a moderate amount of vertigo which gradually disappeared. Following a week in the hospital and three additional weeks of rest, she was able to resume her duties as a public health nurse, which included driving a car in her work.

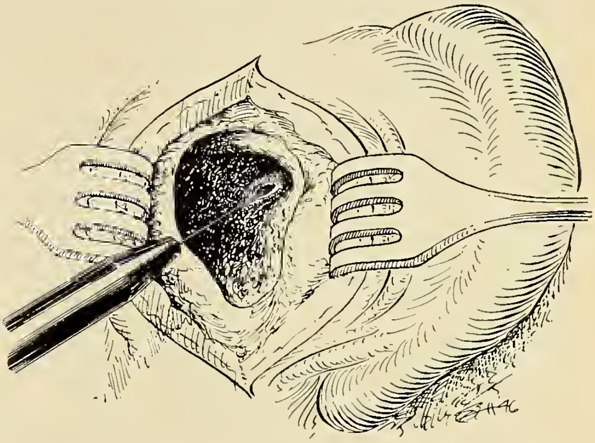

Fig. 2. A sketch of the exposure used to reach the horizontal semicircular canal which is fenestrated by use of a motor-driven dental burr. A small diathermy point is then inserted forward to the vestibule and a weak coagulating current turned on for two or three seconds. The wound is closed tightly and heals by primary union.

(The postaural route is considered to be preferable to the endaural route for these cases, because in the latter a period of epithelization is usually required before drainage ceases from the external meatus. The postaural wound is usually sealed and the ear dry in one week and no further dressing is required.)

The remaining hearing in the operated-upon ear was lost as a result of the operation. She was re-examined on several occasions during the first year following the operation. There was no recurrence of her symptoms.

Case 2.—M. G., a forty-nine-year-old man, a clerk, had had "Ménière's disease" for eight years. He had undergone extensive study and treatment at a United States Veterans Hospital. This included trials of histamine and the Furstenberg method. The patient stated that he had been deaf in the right ear for a number of years and believed that his deafness was due to mumps; he had experienced a ringing as long as the deafness.

Hearing tests revealed an absolute deafness in the right ear and normal hearing in the left ear. Caloric tests after the method of Kobrak revealed a subnormal reaction in the right ear and a normal reaction on the left side.

A labyrinthotomy with coagulation of the membranous labryinth was performed on November 7, 1945. Convalescence seemed slow. The patient seemed to fear a recurrence of the severe vertiginous attacks which he had experienced before this operation. He was last examined ten months after this operation at which time he had experienced no recurrence of his attacks.

Case 3.—J. P., a sixty-six-year-old man, a machinist, was first examined on December 7, 1945, at a hospital where he was convalescing from a gall-bladder operation. This operation had been done to relieve attacks of dizziness. His left ear had begun to "go bad" almost a year previously. The ringing which had been bad in the left ear had decreased somewhat.

Hearing tests revealed a marked loss in each ear—at the 45 decibel level by air conduction for the speech frequencies in the right ear and at the 60 decibel level in the left ear. The caloric tests with water at 68°F.

showed a reaction within normal limits on each side. The patient lived alone and was in imminent fear of an attack. He was hospitalized and given intravenous histamine daily for one week. His vertiginous attacks continued.

A labyrinthotomy was performed on the left ear on January 23, 1946, and the membranous labryinth coagulated after the method of Day. Convalescence was slow but otherwise uneventful. The patient has been free of his vertiginous attacks since the operation.

Case 4.—E. L., a forty-one-year-old man, a deaf mute, had been unable to work because of attacks of vertigo. He had tinnitus in the left ear.

Caloric tests after the method of Kobrak revealed a normal reaction in the right ear and a definitely subnormal response on the left side.

A labyrinthotomy was performed on the left ear on April 1, 1946. Convalescence was uneventful. There was no recurrence of symptoms six months after the operation.

Case 5.—J. L., a man, aged sixty-five, retired, had been incapacitated for one and a half years because of severe attacks of vertigo. He was unable to go out on the street because of fear of falling down. He had had some dizziness fifteen years previously and stated that he had been deaf in the right ear for ten years. He had had some tinnitus in both ears.

Hearing tests revealed a normal level for one of his age in the left ear and a 75 decibel level of air conduction for the speech frequencies in the right ear. Caloric tests after the method of Kobrak revealed no response in the right ear and a normal one on the left side.

A labyrinthotomy was done on the right ear on April 8, 1946, and the membranous labyrinth coagulated with diathermy. Convalescence was slow but otherwise uneventful. To date, this patient has had no recurrence of his vertigo.

Summary

A microscopic study of the temporal bones of a number of persons known to have had Ménière's disease during life has revealed evidence of a labyrinthine hydrops.

When medical therapy (histamine desensitization, the use of a sodium-free diet combined with the administration of ammonium chloride, or treatment with potassium chloride or with nicotinic acid) does not produce relief, a labyrinthotomy followed by coagulation of a limited portion of the membranous labyrinth offers a practically certain cure when the disease is confined to one side.

The labyrinthotomy is a simpler operation than nerve section. The simplest form is accomplished by making a fenestra through the bony wall of the horizontal semicircular canal. If this is followed by mild and limited coagulation of the membranous labyrinth, the symptoms of Ménière's disease are controlled and there is a possibility of preserving some hearing.

Five cases operated upon by the method of Day are reported. Relief from the attacks of vertigo was obtained in each case.

Discussion

Dr. A. M. Snell, Rochester: I should like to compliment Dr. Boies on his excellent presentation of a difficult subject and on his appraisal of the Day operation. I was particularly glad to hear him state his criteria for diagnosis. Much has been said and written about the treatment of Ménière's disease, but in many instances these criteria have not been defined exactly. This practice has tended to cast an unfavorable light on some methods of treatment which have been advocated.

I have had the opportunity of seeing a number of patients whom Dr. Horton has treated with histamine at the Mayo Clinic, and there have been some very encouraging results. When the disease has been of short duration, this therapeutic program seems to work out very well, but many patients with disease of long standing have not been benefited by this or any other type of medical treatment. There are certainly many patients in this last-mentioned group who deserve the possible benefits of the operation which Dr. Boies has described.

Dr. Kenneth Phelps, Minneapolis: Dr. Boies' thesis is an excellent presentation of the most recent ideas concerning Ménière's disease. It brings out several points:

1. The very recent observations on the pathology of Ménière's disease are given although just how hydrops of the labyrinth causes intermittent attacks of vertigo and progressive loss of hearing is not well understood.

2. Even with better knowledge of the pathology, we do not know what causes this disease. Treatment of the cause is, therefore, impossible.

3. Dr. Boies' experience with the Day operation is very hopeful. This procedure relieves the patient of his symptoms by destroying his labyrinth, and, as Dr. Boies very carefully states, "offers a chance of preserving the residual hearing." Hearing is very poor in most patients who have had Ménière's disease for years, so it is not of major importance.

I would like Dr. Boies to tell us what success he has had with medical treatment.

Dr. Hewitt B. Hannah, Minneapolis: I appreciated hearing Dr. Boies this evening because I have had an opportunity of watching some of these patients over the last two years. I had seen one of these patients before he was operated upon, and he was extremely dizzy and had been bedridden for a long time. Dr. Boies operated on him, and since the operation he has been free from symptoms. The other one was a nurse. I did not see her before the operation but I saw her afterward, and she is very happy over her recovery.

The differential diagnosis is not always too easy. Any one who has dizziness, noises in the ear and some loss of hearing should be studied from the standpoint of the nervous system to be sure that the patient does not have an acoustic tumor or pathology in the cerebellum. In the patients whom Dr. Boies operated upon, there had been no evidence of such tumor of the acoustic nerve or pathology in the central nervous system. I understand that Dr. Dandy had operated over four hundred patients by cutting the eighth nerve. Cutting this nerve as it leaves the stem is a much more formidable procedure, and it takes a man with skill of a surgical character, similar to Dandy, to get by with this type of procedure.

Dr. Gordon Kamman, Saint Paul: I was interested in Dr. Boies' approach to Ménière's syndrome. The only reason it is any of the neurologist's business is because of the differential diagnosis. Ménière's disease itself is purely an end organ disease and does not fall within the province of a neurologist. However, certain other conditions have to be eliminated by differential diagnosis before one considers the treatment of Ménière's syndrome. I would like to ask Dr. Boies how many cases he has had of bilateral Ménière's disease. In considering the surgical treatment of this condition, one must always recognize the possibility of the same process occurring on the good side. If hearing is going to be destroyed by surgery, I think that it is very important that the patient knows before operation of the possibility of the same process occurring on the opposite side and the possibility of his ending up with a bilateral deafness. It is my understanding that by coagulation of the horizontal semicircular canal one destroys the hearing in that ear?

I feel that Dr. Boies' approach to the surgical treatment of Ménière's syndrome offers us a great deal. In the few cases that I have had the temerity to treat, I have always been disappointed with the long-range results. True, with intravenous histamine, large doses of nicotinic acid, sometimes the Furstenburg diet, large doses of potassium, and other medical measures, we are able to bring about temporary improvement in the symptoms. However, I think that most cases eventually end as surgical candidates. The simplicity of Dr. Boies' approach, the lack of surgical risk, and the short period of hospitalization certainly are enough to recommend Dr. Boies' operation.

Dr. C. N. Hensel, St. Paul: Dr. Boies has clearly defined his criteria for surgical intervention in patients with persistent vertigo in Ménière's syndrome, namely, failure to relieve them of their incapacitating vertigo by medical management, and he has reported five patients in whom he has obtained complete relief by an ingenious and nonhazardous operation, and therefore he suggests to us tonight that this is the procedure we should choose in such cases.

Having had some experience in the medical management of cases similar to those he has described, I cannot accept as our only recourse an operation which, while it relieves vertigo, renders the operated ear permanently deaf.

People with vertigo in the middle age group are numerous and the majority are not subject to labyrinthine hemorrhage. Most of them appear to be suffering from a momentary functional derangement of the labyrinth due apparently to imbalance of the blood supply with resultant increased local capillary permeability and local edema and labyrinthine hydrops.

It seems that several factors may play a part in this syndrome, i.e., increased retention of the sodium ion with increased retention of fluid, local vasoconstriction and local vasodilatation. Harris and Moore of the Crile Clinic first called attention (in 1940) to the vasoconstriction factor. They recalled that physicians treating pellagrins found a high percentage with rotational vertigo, which seemed to be on a nutritional basis. So these physicians started in to treat their patients suffering from Ménière's syndrome with large doses of thiamine chloride with success. Then they tried treating such patients with nicotinic acid, with unsatisfactory results.

Finally, they combined the treatment and gave thiamine chloride 10 mg. twice daily by mouth and nicotinic acid 50 mg. five times a day, and began to get results. They noted that within two weeks half of their cases began to improve, and within six weeks seventeen out of twenty cases had been entirely relieved and that the final three cases were improved. They were impressed that the majority of their vertiginous patients had peculiar dietary habits, were either vegetarians or carbohydrate addicts, or consumed inadequate proteins due to faulty dentures.

Since reading their article, I have observed and treated at least five patients with Ménière's syndrome, observing strict restriction of sodium chloride and fluids and giving adequate doses of thiamine and nicotinic acid.

One woman who improved has been lost track of since she removed to California. The others have all continued to maintain their equilibrium and be free from vertigo for from two to five years.

The most dramatic patient was a bond salesman, aged fifty-eight, who had to retire in March, 1941, because of attacks of sudden "falling" vertigo. He has been free from attacks of vertigo for the past five years on a low-salt low-fluid diet and has been taking 30 mg. thiamine and 300 mg. nicotinic acid a day. In spite of the fact that he has developed intermittent claudication and his blood pressure has risen from 160/90 to 200/100, he is continuously free from attacks of vertigo.

Therefore, I believe that unless such a thorough-going and meticulous regime has been instituted and failed, we should not have recourse to surgical intervention.

Dr. Boies, in closing: Dr. Phelps asked what experience I had from medical treatment. Most of the patients I have seen with vertigo, tinnitus and deafness have been referred to me by internists or general practitioners and the medical treatment has usually been carried out by them. The mild cases and some that are more severe seem to respond to these various forms of treatment. It has been my observation that the best results have been obtained with histamine. In the University Hospital the cases have been treated by Dr. A. B. Baker, who has given them intensive histamine therapy for fourteen days and then followed this by treatment on alternate days until a total of eighteen treatments have been received. The mild and some moderately severe cases seem to have been controlled in a fair measure. However, there seems to be a lack of permanency to this treatment.

When there is bilateral involvement, it is difficult to differentiate as to the actual site of the phenomenon which produced the symptoms. Fortunately, most of the cases seem to be unilateral. In the cases I have reported, the nurse had gone five years without developing symptoms on the opposite side, and another patient had gone ten years. In cases of marked changes in the ear with extensive dilatation of the cochlear duct, I rather believe that these changes are irreversible.

PERIPHERAL ARTERIAL EMBOLISM

JOSEPH F. BORG, M.D.
Saint Paul, Minnesota

Peripheral arterial embolism presents a problem in diagnosis and treatment which is of challenging importance. Where large vessels are involved, the result is usually gangrene leading to death in approximately 90 per cent of all patients with expectant treatment or amputation. These poor results are emphasized in the experience with this type of case at Ancker Hospital over the past thirteen years, in which eleven cases of peripheral arterial embolism were diagnosed and no recoveries recorded. Such disappointing experiences point to a woefully inadequate awareness of the therapeutic possibilities available and emphasize the need for calling attention to this problem. The results of missionary efforts of this nature are seen in the reports on this subject from Sweden, and it has been well shown that many lives will be saved and amputations prevented where the profession is alert to its responsibility. This thesis attempts to review the significant contributions to the subject and to call attention to the importance of recent advances in the treatment of this condition.

Peripheral arterial embolism presents an emergency of great urgency. It is a condition which is usually seen first by the general practitioner or the internist, especially the cardiologist. It is upon them that the responsibility lies for treatment in which delay cannot be permitted. Recent reports emphasize the value of medical measures, but reliance on them alone is dangerous, and it must be recognized that surgery in the form of embolectomy must always be considered and, where indicated, must be carried out within a time interval which will give the most favorable results. It has never fallen to the lot of any one physician to accumulate a large series of cases, but the consensus as revealed in case reports in the literature points to a modern concept of the condition and its treatment which materially improves the outlook for these patients. The two factors which are most important are early recognition of the condition and the availablity of a surgeon competent to do vascular surgery.

Historical

Until the turn of the century, arterial emboli were only of pathologic interest. The idea of removing the offending embolus had been considered, but it was not until 1895 when Ssabanejeff first attempted the surgical removal of an embolus from the femoral artery in a case of a twenty-eight-year-old woman with rheumatic heart disease. Moynihan (1907) and Handly (1907) next approached it unsuccessfully. In 1907 Stewart reported the first attempt in this country. In 1909 Murphy[30] unsuccessfully operated to remove a femoral embolus four days after the onset. The first successful embolectomy, left femoral, was performed by Lahey in 1911 on a patient thirty-eight years of age with mitral stenosis, on whom operation was performed six hours after the onset. In 1912 Einar Key,[15] in Sweden, did the first of his series of embolectomies on fifteen patients which he reported in 1921 with the first review of the literature, embracing forty-five cases with thirteen successful results. Key so well educated the Swedish profession that by 1927 he was able to report 145 Swedish cases with eighty-six successful results out of a total of 216 cases collected from the literature. So slowly did the American profession become aware of the therapeutic possibilities of embolectomy that in 1928 Pemberton[37] was able to collect only twenty cases reported in the United States and Canada. Even the British failed to heed the work of Key because it was 1925 before the first successful embolectomy was reported in England. Subsequently reviews of the subject have been made by Reed and Andrus (1927), Andrews and Harkins (1932), Pearse (1933), Danzis (1933), Linton (1941), Pratt (1942), Lesser (1943), and notably McClure and Harkins (1943) who have presented the most comprehensive recent review, based on 690 reported cases. The increasingly favorable results of therapy insistently emphasize the need for an enlightened attitude toward the problem.

Incidence

The incidence of peripheral emboli is much greater than the reports would indicate. Many cases of reported gangrene or arterial thrombosis are probably primarily embolic, especially where large vessels, notably those proximal to the radial and popliteal arteries, are involved. Out of 690 embolectomies reported, 382 were Swedish cases collected by Key[16] up to 1936, emphasizing again the attention paid to the condition in Sweden and the inadequacy of domestic reports as a guide to incidence. Murray[31] reported thirty cases in the Toronto General Hospital in five years preceding 1936. Lund[24] found fifty-five cases in the Boston City Hospital in seven years prior to 1937. Forty-six cases were reported by McKechnie and Allen[28] over a ten-year period. Agar[1] reported seven cases in five patients in three years from 28,000 hospital admissions at Leeds. Eleven cases reviewed here have been recorded at Ancker Hospital, Saint Paul, over a thirteen-year period. Incidence is about the same in both sexes.[28] Study of 129 cases by Danzis[4] revealed an average age of forty-nine years, the range being seventeen months to eighty-two years. Most of them occurred between the ages of thirty and seventy, with the peak decade being fifty to sixty years.

Pathogenesis

Arterial emboli are caused by the breaking off of pieces of thrombi, the majority of which come from the left side of the heart. Rarely they may originate from thrombophlebitis or phlebothrombosis and find their way to the arterial tree through a patent foramen ovale. The great majority may be traced to rheumatic mitral or arteriosclerotic heart disease, frequently with auricular fibrillation, in which thrombi form in the left auricle. Others come from mural thrombi which form as a result of myocardial infarction. Danzis[41] states that 70 per cent are of pure cardiac origin and that most of the rest are of cardiac origin associated with some disease such as diabetes, arteriosclerosis, or thyroid disease. Rarely the embolus may come from an arterial thrombus attached to an arteriosclerotic plaque of a large vessel. McKechnie and Allen[28] reported that of forty-six cases, forty-one were of cardiac origin, two from pelvic carcinoma, one had a patent foramen ovale, one was arteriosclerotic, and one followed a cervical rib operation. Pearse,[36] reviewing 296 cases, found the following known source distribution:

	Per cent
Heart disease	69.2
Postoperative states	13.0
Infection and trauma	2.1
Arteriosclerosis	2.1
Aneurysm	1.8
Abortion and delivery	1.8
Miscellaneous	2.8
Phlebitis	0.3

When an embolus is sent out into the arterial tree, it usually passes the hazards of the innominate, left common carotid and left subclavian arteries, the reason for which is not entirely clear. Depending on its size, it then passes on to lodge in some more distant part of the arterial system, usually at a bifurcation. Riddell[39] states that only 12.1 per cent of emboli reach the upper extremity while 87.9 per cent reach the lower.

On lodging, the sudden insult to the artery sets up a reflex arterial spasm which is extremely important in affecting the clinical course and outcome of the accident. After a variable period of time, changes occur in the endothelial wall which lead to the formation of a secondary thrombus. Key[16] states that this thrombus may start as early as two hours after lodgment or may not appear as late as twenty-four hours, the longest reported period between the onset and operation without gangrene. This probably depends on the amount of reflex arterial spasm present and the extent of effective collateral circulation. Linton[21] states that secondary thrombi may occur as early as nine hours. These thrombi propagate distally and may completely plug all the tributaries and ramifications of the vessel, being hard to remove. On the other hand, proximal propagation is usually only a few centimeters and is easily removed.

Emboli experimentally produced by Murray[32] revealed no reaction in the vessel wall at six hours, considerable change with adhesion at twenty-four hours, and a firm thrombolic adherence at forty-eight hours with an invasion of the clot and vascular wall by leukocytes.

Considerable attention must be paid to the role played by reflex arterial spasm in this condition, the relief of which is important in treatment. That traumatic vascular spasm is important clinically has been long recognized but little heeded. The occurrence of this condition following external trauma was first reported in 1915 by Fritz Kroh, and forty-four cases were reported up to 1935 in a review by Montgomery et al.[29] That vascular occlusion will produce the same result is generally accepted. The distally propagated thrombosis following occlusion is often very much narrower than that above the embolus, a fact which can hardly be explained otherwise than by spasm. Also, the experimental and clinical surgical observations of these vessels, together with the clinical relief and return of distal arterial pulsation obtained by vasodilating means, papaverine, local arterial sympathectomy, spinal anesthesia, paravertebral block, and lumbar sympathectomy, point toward this being a pernicious action amenable to treatment which may improve the outlook for circulatory restoration and obviate the necessity for embolectomy.

TABLE I.

Site of Embolus	No. Cases	Per cent
Lungs	113	1.8
Kidney	74	1.2
Spleen	60	1.0
Brain	32	.52
Extremities	15	.24
Intestines	16	.1
Liver	1	.016

TABLE II. PERCENTAGE DISTRIBUTION OF PERIPHERAL EMBOLI

Site	Dickinson (15)	De Takats (16)	Key (3)
Aorta	4.5	10.1	4.5
Iliac	17.0	18.3	17.3
Femoral	5.5	39.1	54.5
Popliteal	11.0	9.8	11.3
Axillary-brachial	12.0	16.0	11.8

Gangrene, usually of the dry type, is the end result of clinically significant peripheral emboli. Due to the excellent collateral circulation of the arm, it is not commonly found here, but where the circulation cannot be restored by embolectomy or by the release of vascular spasm permitting adequate collateral circulation, gangrene is the usual result. This of course necessitates amputation which is often fatal due to the poor condition of the patient as a result of the primary condition and the usually advanced age.

Site of the Embolus

Vascular emboli may lodge in any part of the body. According to Bull,[3] in a study of embolic incidence in 6,140 autopsies, only the intestines and liver showed less of an incidence than the extremities (Table I).

It is noted that the lungs were most commonly involved as would be expected with the much greater probability of occurrence following thrombophlebitis or phlebothrombosis. However, it is not likely that these figures reflect at all the true incidence since the relative care in searching for them varies, and the liklihood of detection is much greater in the case of the brain, spleen and kidneys where much more meticulous search for pathology is made. As shown, the extremities were involved in .24 per cent of all autopsies.

A peripheral embolus usually lodges at the site of an arterial bifurcation where there is a definite decrease in the size of the distal branches. The lower extremity is involved seven times as often as the upper. Table II shows the percentage distribution of emboli in the more important locations as determined by several investigators.

Symptoms

Considerable variation occurs in the initial manifestations of peripheral embolism. Key[16] states that the onset is usually one of sudden pain in the extremity, but from numerous other descriptions it becomes clear that while pain of maximum severity at the outset is probably most common, it is by no means invariable. McClure et al[27] state that premonitory distress may be due to small emboli, not incapacitating, or to the movement of one which has straddled a bifurcation without being large enough to close either branch totally and which later slips into one or the other, causing major symptoms. Johnson[14] states that the initial distress may vary from a numbness to an acute pain, followed later by coldness, tingling, stiffness and paralysis or paresis. Dickinson[8] in reporting five cases stated that four had only slight pain at the onset but that all cases complained of numbness and inability to use the extremity as the first symptom. Rykert et al[41] in a series of thirty-six cases found pain to be initial in 64 per cent. It was of maximum severity at the onset in 53 per cent, the others complaining of minor distress becoming maximal after an interval. Of the latter 47 per cent, pain, numbness and coldness coincided in six cases, while in the remainder the onset produced numbness and coldness followed later by pain.

The course of symptoms is usually that of the pain, numbness, and tingling lasting from twenty-four to seventy-two hours, followed by the lesser distress of ensuing gangrene or by the picture of vascular insufficiency. These latter are dominated by an ischemic neuritis with paroxysms of pain over large areas of no particular nerve distribution, vasomotor changes, hyperesthesia, coldness and intermittent claudication, and occur in those cases with sufficient collateral supply to prevent gangrene but not vascular insufficiency. Volkmann's contracture may be a sequel of this course of events.

The mechanism of pain production is of considerable interest. Two distinct factors are involved and determine the nature of its initial manifestation. Where pain is maximum at the onset it appears to be due to reflex vascular spasm from irritation of the endothelium by the lodging embolus. This pain is sudden, very distressing, aching, and is located over the site of the embolus. The origin of this pain is suggested in its response to measures for the relief of vascular spasm such as papaverine, paravertebral block, and lumbar sympathectomy as well as observations of the spastic state of the involved vessel.

On the other hand, Lewis[19] has nicely shown the part played by ischemia in the production of pain following arterial occlusion. This pain is due to ischemia of somatic musculature. It is not found in the occlusion of vessels serving organs without striated muscle, such as the brain, lungs or spleen. It starts first as a numbness, tingling and coldness with pain occurring later, located principally in a position distal to the level of the actual obstruction. It occurs about thirty minutes following the occlusion, depending on the muscular activity of the extremity involved. This pain is not affected by relief of spasm except insofar as spasm release provides sufficient improvement in the collateral circulation to relieve the ischemia.

Study of the mechanism of pain therefore has pointed the way to the most effective medical measures of treatment available and offers some hope for the satisfactory treatment of a few cases without surgery. This will be further discussed under treatment.

Signs

On physical examination the earliest signs are those of pallor, loss of arterial pulsation and temperature reduction. Pallor is early of a waxen hue, or it may be a marbling. Later it becomes a blotchy cyanosis which comes to show the demarcation limited by collateral circulation. Loss of arterial pulsation is most important in diagnosis and determination of the site of the embolus. Usually the site will be found to be at the bifurcation above the level of loss of pulsation. This, however, may be confusing because, as Agar[1] points out, a long or propagating embolus may show pulsation in the mass at some distance below the lodging place. Thus in common femoral embolus it is possible to have a pulsation below Poupart's ligament. Temperature change, coldness, is a sign as well as a symptom. It, too, is important in diagnosis and is generally easily recognized by gross examination. Skin thermometry is not necessary although it may aid in the determination of the line of demarcation.

Within a short time diminished muscular power leading to paralysis supervenes. With it there are diminished sensory findings with diminution or loss of reflexes. Anesthesia of the stocking type below the site of the embolus may be found.

Several hours after the onset the clinical picture may be confused by the appearance of secondary venous thrombosis. This will cause a tendency to swelling and localized tenderness of previously empty veins.

Gangrene will appear in the cases with untreated or unsatisfactorily restored circulations in degree dependent on adequacy of collateral circulation. This depends on a number of factors including the age of the patient with the varying degrees of arteriosclerosis in possible collateral vessels and the adequacy of the general circulation. In animal experiments Melzner (quoted by De Takats[7]) has shown that where the collateral arterial pressure below the site of ligation is less than 15 millimeters of mercury thrombosis and gangrene result. The incidence of gangrene in reports varies considerably, with marked decrease under modern methods of treatment, both medical and surgical. McKechnie et al[28] reported an incidence of 45 per cent gangrene in a series of forty-six cases of emboli seen over a ten-year period. In this series the age factor is shown in that the incidence was 73 per cent after the age of sixty, and 32 per cent in younger patients.

Differential Diagnosis

While the diagnosis of embolism may be clear cut, difficult or impossible, it is not usually troublesome although at times some confusion may enter. The relatively sudden onset of the described symptoms and signs in an individual with the usual underlying causes should make one immediately suspicious of the possibility. Where the onset is not so abrupt, more difficulty may be encountered. Arterial spasm without embolus may produce a similar picture but this is practically always on a basis of trauma, the history of which can be elicited. Primary arterial thrombosis can also produce this syndrome but practically never occurs above the popliteal, ulnar or radial arteries, and smaller artery obstruction is usually cared for by adequate collateral circulation. Assisting in its elimination is the elicitation of a history of long-standing symptoms of coldness, numbness, intermittent claudication, cramps, and paresthesias months or years before complete obstruction of gradual onset occurs in an individual with arteriosclerosis, often diabetic.

Thrombophlebitis should not be confusing, the local pain and tenderness, the cyanosis, the peripheral edema and increased temperature and the presence of arterial pulsation usually sufficing to identify it. Occasionally in phlebitis the arterial pulse may temporarily disappear due to vascular spasm. Also, the secondary venous thrombosis following arterial occlusion must not be allowed to confuse the picture. Buerger's disease likewise exhibits a clinical picture which is usually not difficult of differentiation although sudden occlusion may be the first symptom.

Arteriography has proved of very little assistance in diagnosis. It may help in locating the site of an embolus, but it is not a practicable procedure and is not considered necessary because the embolus nearly always is to be found at the bifurcation above the level of the physical findings.

Treatment

As McClure et al[27] state: "Because of the urgency of the situation, early diagnosis and prompt decisions are essential. As in perforated ulcer and many other surgical conditions, the number of hours after onset is one of the chief factors affecting the prognosis." Before the use of anticoagulant therapy with or without surgical intervention, this was so true that, by some, embolectomy was considered useless after ten hours. More recently, assisted by the anticoagulants, surgery has accomplished a marked improvement in results, even in cases where treatment was delayed, and embolectomy where indicated can now be done with a far greater promise of success than formerly. "It is never the operation which kills the patient but the disease which makes the operation necessary" (Griffiths[9]).

Medical treatment is always justifiable at the start but should not be carried on alone more than the few hours which will suffice to determine its effectiveness. Relief of pain is effected by opiates, which should not be withheld. The position of the extremity may be important. Formerly it was considered wise to elevate it, but more recently has been accepted the practice of lowering it 10 to 15 degrees to assist the collateral circulation by gravity (De Takats[7] and Barker et al[2]). Whisky has been advocated by Barker et al[2] in doses of 1½ ounces every four hours. It is a good vasodilator. Probably more effective for relief of reflex spasm is papaverine which has come into use in the last decade. After it had been shown that atropin was useless, Denk[5] tried papaverine intravenously in a patient fourteen hours after the onset and noted about thirty minutes later by capillary microscopy a dilatation of vessels which lasted about three hours. Repeating the injections, he observed that after the fourth injection the vessels remained open. He reported ten cases in which it was used, in six of which he obtained good results and in four of which the outcome was not a success. On the other hand, Griffith[9] reports unsatisfactory results from the use of papaverine. No well-controlled series throws any light on its real value, but it seems fair to assume that if results are to be obtained, it will be determined by the result of a single intravenous injection of one-half to one grain of papaverine hydrochloride intravenously. If no restoration of circulation results within an hour, it should be regarded as ineffective.

Sympathetic block has been advocated by Barker et al[2] if papaverine is ineffective. Roome[40] reports the prompt and complete relief of pain following such treatment in two cases, but except for casual mention, it has few champions. Probably it deserves a better trial than it has been afforded, since the results can be evaluated in a short time if papaverine is found useless.

These medical measures deserve carefully observed trial, and since not more than an hour or two need elapse before an adequate evaluation of their results is possible, their use is well justified. In all cases the surgeon should be immediately called and preparations for operative treatment made ready. Where medical measures are unsuccessful, restoration of circulation is possible only by embolectomy. Due to relatively recent introduction of measures to relieve vasospasm and prevent coagulation, the literature dealing with arterial embolism is predominantly surgical. While it is obvious that there is a greater tendency to report good results than poor ones, and while there are no large series of embolectomies performed by one surgeon, sufficient reports are available to establish beyond doubt the effectiveness of the surgical approach in saving lives and limbs. It is not the province of this paper to deal with the technical aspects of surgical treatment which are adequately covered elsewhere.

In 1943, 690 cases with embolectomy were gathered by McClure et al[27] in a comprehensive review with results that are definitely encouraging. As pointed out by Lund[40] the experience of the surgeon in this work is of great importance and it would serve greatly the general results obtained if this work could be concentrated in the hands of one or two surgeons in a community. Lund[24] showed that in a period of six years following the first embolectomy at the Boston City Hospital in 1925, he could divide experience into two periods of three years each. These showed materially improved later results in the second period due entirely to improved skill. In the first three years he had 25 per cent successful results and a 67 per cent mortality, whereas in the second three years he showed 46 per cent successes and 27 per cent mortality. Where the legs only were involved, the earlier group showed 18 per cent successes and 64 per cent mortality, while the latter showed 55 per cent successes and 22 per cent mortality.

In a series of twenty-nine cases without operation, 8 per cent recovered and the mortality was 85 per cent. These figures speak for themselves.

Regardless of experience of the surgeon it is agreed that the most important factor leading to success is the reduction of the interval between onset and operation. Johnson[14] states that results are poor after ten hours, nil after forty-eight hours. Dickinson[8] says they are good under eight hours, poor after twenty-four hours. Agar[1] reports a "reasonable" chance under six hours, with recovery rare after twelve hours. McKechnie et al[28] would avoid delay over three hours, obviously difficult to prevent. Lund[24] reported no successes after nine hours. Murray[31] in an early report of nine successes out of seventeen cases showed that eight of these were in patients operated under six hours. Key,[16] in reporting 382 collected cases with 22.5 per cent good results, found that among those operated upon under ten hours, the outcome was successful in 55.8 per cent. Danzis,[4] in estimating the influence of the time interval between onset and operation on the outcome, found that under four hours 62 per cent showed restored circulation; from four to eight hours, 50 per cent; from eight to twelve hours, 25 per cent; and from twelve to twenty-four hours, 21 per cent. He found no authentic report of success after forty-eight hours, explaining any such successes on probable collateral circulation development.

The foregoing results are those obtained without the use of anticoagulants and comprised the great majority of reported cases up to this time. A new chapter in treatment seems to have been added with the introduction of heparin, which will be discussed later.

While the importance of early diagnosis and treatment cannot be too strongly stressed, it is recognized that very occasionally results may be obtained in cases with delayed operation so that the opportunity should not be denied on that basis alone, especially with the anticoagulants available.

The risk of surgery is relatively small in these cases even though the patients are often very ill and not infrequently quite old. While mortality following operation is not insignificant, it is so much better than in non-interference that operation is rarely contraindicated even though the risk seems grave. Emphasized by McClure et al, Pemberton[37] states, "There is no established operative procedure of equal simplicity, frought with so little risk, with such dramatic potentialities, that has been so woefully neglected as embolectomy." Choice of anesthesia is not difficult. Danzis[4] states that the type of anesthesia is noncontributory to the outcome. Considering the gravity of the underlying disease, it is difficult to accept that without reservations. Local anesthesia, however, is favored by most authors. Regional or block anesthesia was advocated by Danzis. Spinal anesthesia has been recommended by some, but opposed by others because of the hypotension which will further impair an already diminished circulation.

Multiple operations have been necessary in a number of patients who had recurrent emboli, and they have been well tolerated. That recurrent embolism should be treated surgically is well supported by the several cases reported in whom the tendency to embolism stopped and recovery ensued.

The use of anticoagulants has divided the history of treatment of arterial emboli into two periods, that before and that after their introduction. Dicoumarol is too recent to judge its value adequately but the results, in conjunction with heparin, are promising. Heparin, however, has been an outstanding boon to the vascular surgeon, and the results obtained have established its place in therapy. Practically all reports of cases operated upon since 1940 indicate the use of heparin. Discovered about 1916 by Howell, it was not until about ten years ago that a sufficiently purified solution was prepared for satisfactory clinical use. Widely distributed in body tissues, especially lung and liver, its action in the body is probably that of an antiprothrombin. Large amounts of it are liberated in anaphylactic shock making the blood incoagulable for long periods. Its fate in the body is unknown. Experimentally its value in vascular disease was suggested by the results of Murray and Best[33] who found the removal of experimental emboli from dog arteries was always followed after twenty-four to seventy-two hours by thrombus formation plugging the artery, whereas this was prevented in all cases by the use of heparin. Clinically they report an unfavorable case in which operation was undertaken twenty-five hours after the onset of symptoms involving both common iliac and femoral arteries. Removal of the emboli revealed "some stickiness of intima," but with heparin circulation was restored. The patient died on the fifteenth postoperative day, and autopsy revealed perfectly healed vessels. These authors suggest the use of heparin in inoperable cases to prevent further extension of the thrombus and preserve the maximum amount of collateral blood supply. Broth[11] reports a case of tumor (sarcoma) embolus in which he had to reopen his incision four times because of thrombolic plugging of the artery after closure. The fifth clearing of the artery was associated with heparin therapy, local and general, and recovery resulted. Numerous other authors have since attested to the value of heparin in conjunction with embolectomy.

Heparin is administered intravenously. Some workers insist on its continuous administration in an amount sufficient to keep the coagulation time at fifteen minutes, usually requiring a flow of 25 to 30 drops per minute of a saline solution containing 100 milligrams of heparin to 1,000 cubic centimeters. The coagulation time should be tested every few hours to determine the rate of administration. Lesser[18] advocates the use of 100 milligrams of heparin every three hours to avoid the large amounts of fluid given when the continuous flow is used. He states that at the end of three hours the coagulation time is still satisfactorily prolonged. This suggestion has merit, especially in those cardiovascular patients who should have a restricted fluid intake.

Dicoumarol will probably have an important place in therapy in association with heparin. Of recent introduction, few reports are available. Wetherell[42] reports four cases in which it was successfully used. Barker et al[2] report six cases with good results, one patient dying of heart failure as the result of an underlying myocardial infarction. Where used, the dosage must be guided by the prothrombin time, considerable care being exercised to avoid overdosage which may otherwise result. Its disadvantage lies in its delayed action, forty-eight hours or more being necessary to determine how high the prothrombin time will go, and in the marked variability in its action on different patients. Its great advantage lies in its being given by mouth. Heparin is always used with it at the start and discontinued in about forty-eight hours or when the prothrombin time reaches 20 to 30 per cent of normal.

Considering the foregoing, a suggested program of treating arterial emboli is presented:

1. Treatment must be started immediately.
2. Room temperature of 80° to 85° F. is used. Heat is to be avoided.
3. Lower the extremity and wrap in cotton.
4. Give 1 ounce of whisky every three hours.
5. Administer papaverine ½ to 1 grain intravenously.
6. If circulation is not restored in one hour, sympathetic block may be tried.
7. If sympathetic block is not effective, embolectomy is performed following the administration of heparin.

Results

While the results of the surgical approach in the treatment of arterial emboli predominantly attest to its value, consideration must be given to those dissenters who have not been impressed with it and mention must be made of passive vascular exercise as developed by Reid and Herrmann. Rykert et al[41] found embolectomy unsatisfactory and reported 50 per cent restoration of circulation by passive vascular exercise. They advise against embolectomy. Linton,[22] in fifteen cases treated by passive vascular exercise, was able to save the circulation in nine. Lund,[23] in considering the latter, finds no justification for it, but Linton[22] believes it may be of use following embolectomy. There is, therefore, insufficient data to indicate that passive vascular exercise is to be seriously considered. Undoubtedly there are cases with unusually good collateral circulation where medical measures might save an extremity, but too often the latter will leave a vascular insufficiency with ischemic symptoms and signs which might be avoided with modern surgical approach.

The earlier reports of surgical treatment show a considerable variation in results, possibly reflecting in part the variations in experience, surgical ability and individual factors in the patients contributing to success or failure. As previously stated, for a long time embolectomies were reported only by the Swedish workers. In 1921-1922 Key[15] quoted thirteen successes out of forty-five cases. The first embolectomy in Great Britian was reported in 1925, and up to 1934 only twenty cases had been reported there, with 50 per cent success. Key's review[16] of 382 Swedish cases to 1936 showed 59.4 per cent mortality, 22.5 per cent good circulatory results, and 18.1 per cent recoveries after amputation. If only the cases operated upon under ten hours are included, good results were obtained in 55.8 per cent. Nystrom (quoted by McClure et al[5]) reported that of thirty-nine embolectomies performed in one clinic, about half were followed by satisfactory circulation. Griffiths, reporting fifteen years' experience to 1940, had eleven successful results in twenty attempts. Four of these successes involved the arms.

Late studies of surgical results are not common, making the report of Strombeck[42] on late results especially interesting. His collection of 372 Swedish cases showed early results comparable to those of Key.[16] Following these through he states that of the successful results three-fourths of the patients were alive at the end of a year, one-half at the end of three-years, one-third at the end of five years, and one-eighth at ten years. Key,[16] reporting results on forty-eight cases from one hospital, states that most were alive at two to three years, one-third alive at ten years and two were alive after fifteen years.

The American reports have been on the whole less favorable. As late as 1942 Dickinson[8] reported five deaths out of six patients, following embolectomies, four of which were after a greater than ten-hour interval. Out of three cases, Massey and Steiner[26] had two recoveries, in both of which operation was performed within three and one-half hours. Linton[22] reports only four recoveries out of twelve patients. Rykert et al[41] had an unsuccessful experience with eleven embolectomies. They state that they had 20 per cent recovery on symptomatic therapy and did not advise embolectomy. Zierold[44] reported 87 per cent mortality in eleven surgical cases as against 72 per cent in the non-operative cases. Koucky et al,[17] reporting twenty-five cases at Cook County Hospital between 1928-1938, had three embolectomies with three deaths. On the other hand, McClure et al[27] had three successful embolectomies in eight patients. Lesser[18] reported four successful surgical results in three patients after intervals of four and one-half, twelve, thirteen and fourteen hours. Griffiths'[9] series of five patients who were operated upon showed three successful results. One of these, after a seventeen and one-half hour interval, developed an ischemic contracture. Murray[31] reported seventeen operations in a series of thirty peripheral emboli. Nine of these patients made good recoveries (eight were operated upon under six hours), while eight had the circulation restored but died of other causes, some embolic. Lund's experiences[24] at Boston City Hospital, fifty-five peripheral emboli in seven years, showed no successes after nine hours had elapsed. Among those not operated upon, 8 per cent recovered while 35 per cent of twenty-seven operated upon recovered.

While these results stress the value of early operation, the reported satisfactory outcomes[13] after thirty-nine and twenty-seven hours without anticoagulants, show that delay alone does not contraindicate surgery, even though the chance of success is small.

The most significant era of surgery in arterial embolism seems to have been opened in the last few years with the introduction of anticoagulants as adjuncts to surgery, and the few reports available show a marked improvement in results from embolectomy. It has been possible to collect fifty-two cases in which heparin has been used, a few in conjunction with dicoumarol. Fifty recoveries are reported. While controlled series are not available, the reports leave little doubt as to the results. Among the earliest advocates of heparin therapy, Murray and Best[33] in 1938 reported five embolectomies with four recoveries. In 1940, Groth[11] reported a case in which a sarcoma tumor embolus was removed from a femoral artery in which thrombus occlusion occurred at the site of and immediately after closure of the artery four times. Following the fourth thrombosis heparin was used locally and intravenously and a satisfactory result was obtained. McFarlane[25] reported a case of mitral stenosis in which four successive emboli were treated surgically and heparinized with good results, after which no further episodes occurred. Lindgren and Wilander[20] reported eight embolectomies with seven successes, in one of which operation was performed after a four and one-half day interval. Ravdin and Wood[38] described a successful operation on a saddle embolus of the bifurcation of the aorta.

Lesser,[18] using 100 mg. of heparin every three hours reported four successful operations following four and one-half, twelve, fourteen and thirteen hour intervals. Murray[34] described seventeen embolectomies in which the circulation became and remained normal in all. This is the most impressive series of heparin treated embolectomies. Later he[35] described five consecutive successful aortic embolectomies. One of these was especially interesting in having three other emboli, two femoral and one cerebral, with recovery from all. The recurrences all came several days after heparin associated with previous operations had been stopped. Two of his patients developed further emboli in spite of heparin and died.

Reported from so many diverse authors, these results of embolectomy with heparin treatment are remarkable in comparison with the earlier results reported.

Report of Cases

The following experiences with peripheral arterial emboli at Ancker Hospital, St. Paul, have prompted the present discussion of the subject.

Case 1.—Mrs. E. G., aged seventy-seven, with diabetes and congestive heart failure, was admitted to the hospital three days after the onset of pain in the left leg, with absent femoral pulsation in a cold, white leg. She was moribund and died forty-eight hours later.

This patient is obviously an example of neglect in early care and in her moribund condition not a subject for embolectomy.

Case 2.—Mrs. A. G., aged sixty-four, with hypertensive heart disease and auricular fibrillation, was admitted to the hospital with severe pain of sudden onset in the left leg of twenty-four hours' duration. The leg was cold with blotchy cyanosis and no pulsation below the femoral artery. Embolectomy was suggested thirty hours after onset but refused by the surgeon. Amputation one week later was followed by gangrene in the stump and death occurred after one month.

While this was a comparatively late case, embolectomy should probably have been attempted.

Case 3.—Mrs. W. C., aged sixty-one, with rheumatic mitral and aortic valvular disease, was in the hospital convalescing from congestive heart failure. On April 30, 1941, she was awakened with severe pain in the right foot followed by numbness of the leg with coldness, pallor and marbled cyanosis. No arterial pulsation in the femoral artery or lower could be elicited. A line of demarcation appeared below the knee. Symptomatic treatment was given. Death occurred nine days later. Autopsy showed thrombus formation in the right external iliac artery and the left auricle.

This case offered a favorable opportunity for embolectomy which should have been tried in the absence of response to symptomatic therapy.

Case 4—Mr. F. A., aged fifty, with no significant history, was well until the onset of a diarrhea three days before admission to the neurological service on June 5, 1943. Three hours before admission, pain of gradual onset appeared in the right hip, progressing to an excruciating character. On admission the leg was cold, paralyzed and the pulses not felt. A diagnosis of embolism was made, but a surgeon was not consulted. Nine hours later he developed severe lower abdominal pain with diarrhea and died nine hours later. Autopsy showed thrombosis of the common iliac artery extending 6.5 centimeters into the aorta. There was also a purulent pericarditis and pyelonephritis.

Here again was a case where clinically the indications for surgery were present. The general condition as revealed at autopsy would doubtless have prevented recovery, but they were not diagnosed antemortem.

Case 5.—Mr. J. L., aged fifty-nine, with history of a stroke in 1939, was admitted October 21, 1941, to the surgical service with severe pain of sudden onset and coldness of the left leg of two days' duration. Surgery was not considered, dry gangrene resulted and supracondyloid amputation was performed November 4, 1941. The patient died one week later. Autopsy showed marked coronary disease with left ventricular mural thrombus, and the pathologist considered the leg lesion to be thrombotic.

The relatively late appearance of this case mitigated against a successful surgical result, but it probably should not have been considered hopeless.

Case 6.—Mrs. A. B., aged sixty-two, was admitted to the hospital June 1, 1939, with a history of hypertensive heart disease with decompensation. Twenty-four hours before admission she experienced pain in the right foot, followed by numbness and shooting pain in the leg. Examination showed congestive heart failure and numbness and coldness in the right leg below the inguinal ligament. Pulse, which was felt in the femoral artery, stopped 2 inches below the inguinal ligament. Surgery was not considered, and symptomatic therapy (including papaverine) was unsuccessful. Death resulted June 28, 1939. Autopsy revealed rheumatic mitral endocarditis and occlusion of the right common iliac artery.

Again, while twenty-four hours elapsed before seen, this patient might have benefited by surgery. The occlusion when first seen was below the level of the inguinal ligament, being later propagated proximally to involve the common iliac artery.

Case 7.—Mrs. J. E., aged twenty-six, a hospital patient with pulmonary tuberculosis and rheumatic heart disease, on August 22, 1940, complained of severe pain in the right leg, alternating with numbness. The leg was white and waxy. Surgery was not considered, and death occurred twenty-four hours later. Autopsy was denied.

This was the second case in which recognition of the embolus was possible almost immediately after the lodgement, and the patient was probably a likely candidate for surgery. The tuberculosis did not appear to be a contraindicating factor.

Case 8.—Mrs. H. L., aged seventy-six, with a diagnosis of coronary arteriosclerosis and cardiac decompensation, was admitted to the hospital six hours after the onset of pain in the left hand, followed by coldness and pallor in the arm, with no arterial pulsation in the axillary artery or distally. The surgeon was not consulted. She was treated symptomatically and died sixty hours later. Autopsy was denied.

This patient would probably not have benefited by operation in view of the failure to live longer than sixty hours following admission. Seen early, however, she should probably have had the opportunity of attempted embolectomy.

Case 9.—Mrs. J. O. D., aged thirty-five, was well until admission for a stabbing pain in the rectum and lower back, the onset of which was twelve hours before she was seen. This pain radiated to the back of both legs and was associated with numbness, coldness, paralysis, absent femoral pulsation, and mottled discoloration of the left leg to the knee. After a short period of improvement of the heart and general condition, she pursued a downhill course to death in two weeks. Autopsy showed a left common iliac occlusion, mitral stenosis, recent myocardial infarction and ventricular mural thrombus.

This patient in retrospect appears to have been a good candidate for embolectomy when first seen. Operation was apparently not considered.

Case 10.—Mr. M. D., aged seventy, with no significant history, was admitted two weeks after the sudden onset of a severe pain in the right leg which later turned blue and cold. A line of demarcation was present below the knee. He had coronary heart disease with auricular fibrillation. Death occurred twenty-four hours after admittance. Autopsy was refused.

This patient was obviously not a candidate for surgery.

Case 11.—Miss E. E., aged seventy-six, with mitral stenosis and auricular fibrillation, had had a severe pain in the right arm three weeks before admission, followed by inability to use the arm. One day before admission she had a similar severe pain in the left leg. No pulsation was found in the right axillary and left popliteal arteries and tributaries. Severe pain persisted in the leg and arm. Operation was not considered. Symptomatic treatment was used, and the patient died one month later after a gradual downhill course. Autopsy was denied.

This patient did not develop gangrene, and it is difficult to determine the effect of the emboli on the outcome. It is likely that an operation would not have altered the clinical course, but embolectomy might have added much to her comfort. Indications for surgery must be regarded as questionable in this case.

Three cases of gangrene were noted in the records in which emboli may have been the etiology. In one of these there was thrombosis of the aorta and common iliac arteries while in another there was thrombosis of the external iliac artery. In all three the clinical histories could have been interpreted as indicating embolism.

A review of this unimpressive collection of failures in treatment reveals several deficiencies which are not uncommon where the profession is not alert to the problem. Delay in admission is not always the fault of the physician, but it is not uncommonly so. One patient was obviously not amenable to treatment, having been admitted two weeks after the onset. Two patients were admitted after two to three days' delay; three were admitted after an interval of twenty-four hours. In the light of earlier experience these would not have been considered good candidates. On the other hand, two patients developed their emboli while in the hospital, and three were seen after intervals of three, six, and twelve hours respectively. These should all have been considered for surgery. A more serious indictment, however, is the lack of consideration of the surgical approach. In only one case was the surgeon asked to see the patient and in this he advised against surgery. In only one case was the patient admitted to the surgical service, and that after an interval of twenty-four hours. Operation was not considered. In all other cases the patients were admitted to non-surgical services and operation was never considered. First among the lessons to be gleaned from this study, and important if nothing else is learned, is the fact that the profession is insufficiently alert to this problem and much may be gained by intelligently directed dissemination of information in this direction.

Discussion

Location of an embolus necessitates certain considerations in treatment. Greater risk than is apparent may be associated with involvement of the popliteal artery because of the danger to the collateral circulation about the knee. Special consideration to emboli in the arm is necessary because of the better collateral circulation available. It is believed by several (Lund, DeTokats) that operation in an upper extremity is seldom indicated. Lund's analysis[24] showed that embolectomy in the arm is twice as likely to be successful as in the leg although the ultimate results, as far as life is concerned, show little difference if no operation is performed. Gangrene did not occur in Lund's non-operative cases, doubtless influencing greatly his opinion. Gangrene, though infrequent, does, however, occur in the upper extremity and there must be considerable doubt as to the wisdom of non-operative treatment in the arm if medical treatment over a short time is not successful.

Embolism in the aorta deserves special recognition because of its serious implications when not operated upon and because of the promising results from operation. Spontaneous recovery is rare but has been reported. In 1921 Hesse[12] collected a series of forty-two cases, the embolus being located at the bifurcation in twenty-five cases, in the abdominal aorta above the bifurcation in twelve, and in the thoracic aorta in two. Sudden death was rare, over half living a week or more. Griffith[9] in 1938 collected reports of 128 cases, twenty-seven with operations and nine successes. The latest available collection is that of McClure[27] in 1943, who found seventeen successful cases. The most impressive group is that of Murray,[35] who reports five successful cases, in all of whom heparin was used. There is some difference of opinion as to the surgical technique, but the consensus is that the extraperintoneal abdominal approach is advisable. With a prepared surgeon at hand, the treatment of aortic embolism at the present time appears promising.

The recent report of Barker et al[2] in which medical treatment is advocated and a series of six consecutive recoveries reported, with no failures, is extremely interesting. Nothing approaching this has been reported elsewhere, and their recommended regime, which is essentially that advised earlier in this paper (except that they would wait twelve hours for relief or spasm), certainly merits trial. These patients had waited as long as twenty-four hours before therapy was started. It must be noted that the authors did not claim that recovery meant an entirely normal circulation, for usually persistent impairment or absence of arterial pulsation or evidences of mild to moderate arterial insufficiency with ischemia remained. Function, to a degree only, was restored in all. Such limitation of response must temper one's enthusiasm for medical treatment especially in view of the good results, as regards adequate circulation, reported by Murray.

Further experience with surgical approach assisted by heparin and dicoumarol will indicate how long it is safe to risk medical treâtment. It would seem possible to determine the results of antispasmodic therapy within a few hours' time, placing less of a risk on the surgical treatment when it becomes necessary.

Summary

The complete failure to save a single life in the complete series of eleven cases of peripheral arterial emboli in a large municipal hospital over a period of thirteen years is analyzed.

The factors predisposing to unsatisfactory therapy are:

1. Failure in calling early medical attention.

2. Lack of prompt hospitalization and medical care when first seen.

3. Lack of general awareness of medical treatment on the part of the general practitioner and internist who see the cases first.

4. Lack of awareness of the satisfactory results which surgery can provide.

5. Lack of surgeons properly trained and interested in this problem.

A review of broad cross-section of experience with this problem is given.

A plan is outlined for the treatment of peripheral arterial occlusion that promises much more successful results in these cases than have been heretofore obtained.

Discussions

Dr. A. A. Zierold, Minneapolis: It has been extremely interesting to hear this excellent review of a subject which should be of considerable interest to everyone.

Dr. Borg has stated that peripheral arterial embolism is much more common than we are led to believe. I believe this statement can be borne out by each one's personal experience if carefully recorded. Some years ago, at the instigation of Dr. George Fahr, I became interested in arterial embolism and in the course of about eighteen months collected twenty-eight cases which were treated surgically and which were reported. During the years following, I have accumulated fifteen or sixteen more. As my interest has subsided, I have seen fewer and fewer cases. The basis for any remarks which I may have to offer is this personal experience.

All of the cases to come under my observation were secondary to some cardiac disorder and the arterial embolus was in each instance a fragment of some cardiac thrombus. Following the lodgment of an embolus at some narrowed point in the artery, usually a major bifurcation, what is called a secondary thrombus develops. Properly speaking, this is not thrombus but intravascular clotting, which is characterized by the appearance of fibrin threads. It is this long distal clot which most often defeats any surgical procedure. As Dr. Borg has stated, it is common experience that the majority of arterial emboli lodge in the lower extremity at the bifurcation of some major vessel. The diagnosis of peripheral arterial embolism is relatively simple. The cardinal points Dr. Borg has emphasized. The difficulty in treatment is to impress on the house staff the necessity for early diagnosis. When gangrene becomes evident, treatment is limited to amputation. There are several methods of determining the location of a peripheral embolus and the extent of the damage incurred. Of these, I believe the best to be palpation of the affected vessel itself. Irrespective of oscillometer readings, color or temperature changes, a peripheral embolus can be located definitely by the following rule: If a peripheral arterial embolus exists, it will be found at the first major bifurcation above which there is pulsation. For example, if a femoral pulse can be felt above the profunda femoris but not below, the embolus will be found at the union of the profunda femoris with the main trunk.

The prognosis in the surgical treatment of embolism is dependent upon two factors, elapsed time following onset and the degree of occlusion of the vessel following the lodgment of the embolic mass. If the artery is suddenly and completely occluded by an embolus, no clots, either proximal or distal, will form. If, however, the vessel is incompletely blocked and there is a leakage about an irregularity of the embolus, a long tail-like clot will form which cannot be removed from the distal portion of the artery. In either event, the shorter the elapsed time the better the prognosis. In occlusion of the major vessels of the upper extremity, it has been my experience that surgical treatment has not been necessary. Likewise, emboli at the bifurcation of the popliteal vessel, if untreated, rarely result in gangrene. If gangrene does develop, it is unusual that more than the tips of the toes are lost. In my hands, the surgical treatment of emboli at this point is no better, if as good, as medical treatment. In my own cases, 75 per cent survived operation but of all the cases only 30 per cent maintained adequate circulation through the affected vessel. It is probable that, with a careful use of heparin, dicoumarol, and papaverine, this figure will be considerably increased.

Dr. Moses Barron, Minneapolis: Dr. Borg presented a very interesting paper on the embolic phenomena in peripheral blood vessels. He showed that we cannot be too optimistic about the results of present-day treatment although the use of anticoagulants seems to have improved the results. My experience with this type of case is very small. In two cases in which I was associated where embolectomy was performed, both patients died. In one case treated medically, the patient survived. This patient had been seen several weeks previously, and she was suffering with an advanced case of heart failure. One day I was called and informed that the patient had suddenly developed pain in one leg with resulting numbness. She was sent to the hospital where I saw her about twelve hours after the onset. I gave her papaverine subcutaneously, applied warmth and raised the head of the bed about 12 inches. The foot appeared cold and the patient could not move either the foot or toes. She appeared very weak, almost in shock. She complained of pain in the foot especially at night. The next morning when I saw her the leg had turned a grayish cyanotic color and this at once showed the seriousness of the condition. The next day blotches were scattered over the leg from the knees downward and the line of demarcation was present around the leg just below the patella. I had been in Toronto several weeks previous where there was presented a method of treatment of peripheral vascular disease which appeared to be promising. Since the method caused no serious reactions, I decided to try it on this patient. I mixed 25 c.c. of ordinary anesthetic ether with 1,000 c.c. of normal saline and added 150 mg. of niacine. This mixture was given intravenously very slowly so that it would take at least two hours to run in. The next morning the leg appeared definitely better; on the second day after the treatment the discoloration had completely disappeared and only faint blotches remained. The patient was feeling better. The blocking of the artery appeared to be just below Poupart's ligament at about the bifurcation of the profunda femoris. No pulsation was evident anywhere below this point. She was given twelve daily injections, then a rest of a week and then another dozen injections. The change in the circulation was most striking. The color of the leg returned to normal, she was able to move the foot and wiggle the toes. However, no pulsation appeared in the arteries. I then started sitting her up with the feet dangling. At first this caused much pain; the length of time of sitting up had to be increased very slowly. Because of the financial status of the patient, I had to send her to the General Hospital for further treatment. Several weeks after her admission there, I was informed by the resident that she was getting definitely better.

This case shows what this type of treatment can do in arterial obstruction. Of course, one does not know the final result yet. I would strongly urge the use of this method of treatment for peripheral vascular disease. Even ulcers seem to respond well to this method. The crust and discharge of ulcers may be cleared up by spraying with ether and applying ether packs on cotton.

Dr. Gordon Kamman, Saint Paul: One of the cases which Dr. Borg mentioned was in Ancker Hospital and on my service. I saw this patient about six hours after the onset of the arterial embolism which, in this case, was in the popliteal artery. It is one of the cases for which the surgeons did not do anything.

I would like to ask Dr. Barron and Dr. Borg what becomes of the embolus when medical treatment is used? Is the embolus dissolved, does it canalize, or does it just seem to vanish?

Dr. Barron: The theory of this treatment is that the injection causes an increase in the collateral circulation. The amount of canalization of thrombosed vessels is often very great. I recently had a patient who developed complete thrombophlebitis of the jugulars on the left side of the neck. She was at the time confined to bed with acute rheumatic fever. She was given dicoumarol for several days and then it was stopped. Subsequently the jugular veins appeared to be back again to normal with apparently a complete absorption of the thrombosis. It is, therefore, possible to have extensive canalization of the clot.

◆ Reports and Announcements ◆

AMERICAN ASSOCIATION ON MENTAL DEFICIENCY

The seventy-first annual meeting of the American Association on Mental Deficiency will be held at the Lowry Hotel, Saint Paul, Minnesota, May 28-31, 1947, inclusive. The association has a membership from the fields of medicine, psychology, education and social work.

All interested persons who are not members are invited to attend. A fee of 50 cents will entitle them to admission to any and all meetings. There will be an open meeting Wednesday night, May 28, in the ballroom of the Lowry Hotel, for which there will be no charge.

Dr. Edward J. Engberg, Minnesota School of Feeble Minded, Faribault, Minnesota, is national chairman on Membership and co-chairman of the Arrangements Committee.

AMERICAN COLLEGE OF PHYSICIANS AND SURGEONS

President of the Minnesota Chapter of the American College of Physicians and Surgeons, a society for general practitioners, is Dr. F. G. Benn, Minneapolis.

Other officers are Dr. A. J. Lewis, Henning, and Dr. Stanley Kucera, Lonsdale, vice presidents, and Dr. A. E. Ritt, Saint Paul, secretary-treasurer. Dr. Charles Donaldson, Foley, is president-elect.

Originated less than a year ago, the American College of Physicians and Surgeons is made up of general practitioners, with its main purpose to inform the family doctor of the practices and problems facing the general practitioner. In addition to the state organization, regional chapters have been formed throughout the state.

Saint Paul Regional Chapter.—Officers of the Saint Paul chapter are Dr. A. E. Ritt, president; Dr. James L. Benepe, president-elect; Dr. E. J. Fogelberg and Dr. C. C. Cooper, vice president; Dr. G. P. Wenzel, secretary-treasurer; and Dr. E. V. Davis and Dr. P. C. Roy, members of the board.

Fergus Falls Regional Chapter.—Organized in October, 1946, the Fergus Falls chapter has as its officers Dr. Edward W. Humphrey, Moorhead, president; Dr. C. H. Pierce, Wadena, president-elect; Dr. S. B. Seitz, Barnesville, and Dr. C. J. Lund, Fergus Falls, vice presidents; and Dr. E. C. Hanson, New York Mills, secretary-treasurer.

CRIPPLED CHILDREN'S CLINICS

Crippled children of Minnesota will have an opportunity for medical examination and advice at eleven district clinics to be conducted by the Crippled Children's Services of the Minnesota Division of Social Welfare, Jarle Leirfallom, director, announced this week.

These clinics, which are a part of the year-round service financed by the federal and state government, are for crippled children and young people under 21 years of age. Vocational tests and advice will be given to those over fourteen years of age.

The schedule for the clinics is as follows:

Worthington, March 29—serving Nobles, Jackson, Murray, Rock, Pipestone, and Cottonwood counties.

St. Cloud, April 12—serving Stearns, Benton, and Sherburne counties.

Austin, April 19—serving Mower, Freeborn, Steele, and Dodge counties.

Thief River Falls, April 25—serving Pennington, Marshall, and Red Lake counties.

Thief River Falls, April 26—serving Roseau and Kittson counties.

Detroit Lakes, May 3—serving Becker, Clay, and Mahnomen counties.

Virginia, May 9—serving St. Louis and Koochiching counties.

Grand Rapids, May 10—serving Itasca and Cass counties.

Brainerd, May 17—serving Crow Wing, Wadena, Todd, Cass, Mille Lacs, and Aitkin counties.

Faribault, May 24—serving Rice, Goodhue, Scott, and Dakota counties.

Morris, June 7—serving Stevens, Pope, Douglas, Grant, Traverse, and Big Stone counties.

Moose Lake, June 14—serving Aitkin, Carlton, Pine, Kanabec, Lake, and Cook counties.

Two orthopedic surgeons, a pediatrician, vocational rehabilitation workers, public health nurse, physical therapists, other nurses, and medical social workers are included on the staff.

The following organizations are co-operating with the Crippled Children's Services in the clinic program: Minnesota-Dakota Orthopedic Society, Northwestern Pediatric Society, Minnesota Public Health Association, Gillette State Hospital for Crippled Children, Division of Vocational Rehabilitation, the Minnesota State Medical Association and the local Medical Society.

MINNESOTA PATHOLOGICAL SOCIETY

The regular meeting of the Minnesota Pathological Society of the University of Minnesota Medical School was held on Tuesday, March 18, in the Medical Science Amphitheater. Dr. A. B. Baker spoke on "Bulbar Poliomyelitis: New Interpretations of the Clinical-Pathological Picture." Dr. M. B. Visscher then spoke on "Physiological Problems in Poliomyelitis."

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

The regular dinner meeting of the Minnesota Society of Neurology and Psychiatry was held at the Town and Country Club, Saint Paul, on Thursday evening, March 11, 1947.

The following were accepted into active membership: Drs. Philip K. Arzt, Kendall B. Corbin, Donald R. Reader, Marvin Sukov, and Leonard A. Titrud.

IN CONSTIPATION OF PREGNANCY . . .

"SMOOTHAGE" MANAGEMENT

Pressure on the pelvic bowel by the enlarged uterus and impaired abdominal muscle tone account, to a great extent, for the high incidence of constipation in pregnancy.

Smooth, gentle, normal evacuation—the desired action in pregnancy constipation management—is afforded by the "smoothage" of Metamucil.

By providing soft, plastic, water-retaining bulk, Metamucil promotes normal, easy peristaltic movement.

Metamucil is the highly refined mucilloid of Plantago ovata (50%), a seed of the psyllium group, combined with dextrose (50%), as a dispersing agent.

METAMUCIL

Dr. Edmund W. Miller presented his inaugural thesis on "Personality Changes Observed in Prefrontal Lobectomized Patients." Dr. Reynold A. Jensen read a paper entitled "The Emotional Factors in Ulcerative Colitis in Children."

HERMAN JOHNSON MEMORIAL LECTURE

Dr. Frank G. Dickinson, economist and insurance specialist who recently became director of the Bureau of Medical Economic Research of the American Medical Association, has been selected to give the annual Herman Johnson Memorial lecture to the senior class of the medical school at the University of Minnesota.

This lecture, which has been given each year since 1938 in memory of Dr. Herman M. Johnson of Dawson, is provided for in a fund established by the House of Delegates of the Minnesota State Medical Association soon after Dr. Johnson's death in 1935.

The address this year is to be given May 28 at 4 p.m., in the large amphitheater of the medical school on the University Campus.

In view of Dr. Johnson's deep interest in medical economics and social problems, the subject for this lecture and the speaker are usually chosen from the economics field or from the field of public service. Dr. Dickinson is particularly well qualified to give the type of message which this lectureship calls for. Famous for his football rating system which he developed as a hobby, Dr. Dickinson has long been associated with economics—as a teacher, an author and an insurance consultant.

Dr. Dickinson is currently making an intensive study for the American Medical Association of the problem of equalizing the supply of and demand for medical service in this country.

The Johnson Lectureship will be Dr. Dickinson's third appearance in the Twin Cities. His first visit was in 1940 when he came to award the Rockne Memorial trophy to the University of Minnesota; his second, his appearance at the banquet of the County Officers meeting, held in Saint Paul in March of this year.

REPORT OF HOUSE OF DELEGATES AMERICAN MEDICAL ASSOCIATION

(Continued from Page 423)

By and large, having a House of Delegates meeting in the interim between regular meetings of the American Medical Association provides the delegates with an excellent opportunity to concentrate on business affairs without any outside interference or attractions. It is hoped that every physician who possibly can will make arrangements to be in Atlantic City in June to attend the centennial celebration of the American Medical Association.

W. A. Coventry, M.D.
A. W. Adson, M.D.
E. W. Hansen, M.D.
F. J. Savage, M.D.

WOMAN'S AUXILIARY

AMA AUXILIARY BULLETIN

A few more months and the members of the Woman's Auxiliary to the American Medical Association will be arriving in Atlantic City, New Jersey, for their annual convention, June 9-13.

Have you made your reservation? If not, send your request at once to Dr. Robert A. Bradley, Chairman Subcommittee on Hotels, 16 Central Pier, Atlantic City, New Jersey.

HENNEPIN COUNTY

The annual Public Relations meeting was held at the Medical Arts Lounge March 7, with Mrs. Frank T. Cavanor as general chairman.

Representatives from many women's organizations were guests, to hear a lecture on "Hormones from Adolescence to the Prime of Life," by Dr. Nora Winther, gynecologist at the University of Minnesota Student Health Service.

Mrs. Elmer M. Rusten gave a talk on health bills in the Minnesota Legislature.

MOWER COUNTY

Mrs. F. H. Rosenthal was hostess to the Woman's Auxiliary of the Mower County Medical Society, February 24, at her home.

Mrs. P. A. Lommen reported on the last co-ordinating council meeting. Council dues were paid, and Mrs. L. G. Flanagan made a motion that each member pay $2.00 toward the auxiliary project of the year and $1.00 to the Cancer Control Fund.

RANGE MEDICAL AUXILIARY

Organization of the Range Medical Association Auxiliary took place in Hibbing on February 13, when wives of physicians belonging to the Range Medical Association held their initial meeting at the home of Mrs. Robert L. Bowen.

Attended by representatives from Virginia, Buhl, Chisholm, Keewatin, Grand Rapids and Hibbing, the meeting brought into being an organization which automatically becomes a branch of the St. Louis County and Minnesota State Medical Auxiliaries.

The constitution and by-laws of the State Medical Auxiliary were read by Mrs. Robert Murray, who also briefly reviewed the histories of four medical auxiliaries of which she has been a member. To simplify future work, it was decided that all officers serving at one time should be from the same geographical section of the Range. Hibbing was chosen to be the first district under this plan.

Mrs. Robert L. Bowen was selected as chairman of the Nominating Committee and was instructed to prepare a slate of officers for the election to be held at the next meeting. As members of her committee she named Mrs. L. W. Johnsrud, Hibbing; Mrs. Edward T. Clark, Buhl; Mrs. Clarence Jacobson, Chisholm; Mrs. E. R. Loofborrow, Keewatin; and Mrs. L. W. Morsman, Hibbing.

In Memoriam

DOMNICK PATRICK DEMPSEY

Dr. Domnick P. Dempsey, of Kellogg, Minnesota, died November 30, 1946, at St. Mary's Hospital, Rochester, following a fracture of the hip sustained in a fall. He was seventy-six years of age.

Dr. Dempsey was born at Clermont, Iowa, on September 9, 1870. After receiving a B.S. degree from Valparaiso University in 1903, he obtained his medical education at Creighton Medical School in Omaha, graduating in 1906. He interned at St. Mary's Hospital in Minneapolis, and opened an office in Kellogg, Minnesota, and in Wabasha, Minnesota, in conjunction with Drs. Lester and Doherty in 1907.

He was elected president of the Wabasha County Medical Society in July, 1912. The subject of his presidential address at the annual meeting in 1913 was "The Press as a Factor in Public Health Work." Again elected president in 1928, he entitled his address in 1929, "Let Us Try," which was a plea for all members of the medical profession to live up to the highest principles of professional ethics. In 1942 he was elected vice president of the society, and in 1943, in the absence of the president who was serving with the armed forces, Dr. Dempsey again gave the presidential address, which was entitled "A Few Remarks on Obstetrics," relating some of his interesting experiences during thirty-six years of practice.

At the time of his death, Dr. Dempsey was on the staff of St. Elizabeth's Hospital, Wabasha, and was an affiliate member of the Wabasha County Medical Society, the Minnesota State and American Medical Associations.

He is survived by a sister who lives in Dubuque, Iowa, and by several nephews and nieces in Iowa and Nebraska.

* * *

Note: More complete information having been received on the life of Dr. Dempsey, since publication of the obituary in the February issue, and in order to correct the mispelling of his first name, this second sketch of his life is published in this issue.

WALTER I. LILLIE

Dr. Walter I. Lillie, former associate in ophthalmology at the Mayo Clinic and since 1933 a resident of Philadelphia, died suddenly on February 21, 1947.

Dr. Lillie was born November 5, 1891, at Grand Haven, Michigan. He received his M.D. degree at the University of Michigan in 1915 and the degree of M.S. in ophthalmology from the University of Minnesota in 1922. He interned at the University of Michigan Hospital in 1916 and practiced at Flint, Michigan, before joining the Mayo Clinic in 1917. At the time of his death Dr. Lillie was professor of ophthalmology at temple University School of Medicine and head of the Department of Ophthalmology at Temple University Hospital, Philadelphia.

Dr. Lillie was certified as a specialist in ophthalmology in 1929 and was a member of the American College of Surgeons, the American Ophthalmological Society, and the American Academy of Ophthalmology and Otolaryngology.

In 1932 Dr. Lillie spent six weeks in Shikarpur, India, at the Seth Heranand Charitable Eye Hospital and shared in the operative work of the annual clinic being held by Mr. H. T. Holland, F.R.C.S.

He was married on August 30, 1916, to Opal C. Jones, who survives him. His brother, Dr. H. I. Lillie, is chief of the Section on Rhinology and Otolaryngology of the Mayo Clinic.

WINFORD PORTER LARSON

Dr. Winford Porter Larson, Professor of Bacteriology and Immunology at the University of Minnesota died, January 1, 1947 of staphylococcic bacteriemia. Dr. Larson was born at Poy Sippi, Wisconsin, March 7, 1880. He received the M.D. degree from the Illinois Medical School in 1904, and afterwards spent seven years in postgraduate study at Berlin, Paris, Vienna, and Copenhagen. He was appointed Instructor in Bacteriology and Immunology at the University of Minnesota in 1911, and was made Head of the Department in 1918. He was a member of the Society of Bacteriologists, the Association of Pathologists and Bacteriologists, and the Association of Immunologists. During his long career he developed a strong department at Minnesota which embraced fundamental bacteriological studies as well as Medical Bacteriology.

BORCHERDT MALT EXTRACT CO., 217 N. Wolcott Ave., Chicago, Ill.

His published scientific papers covered a number of subjects and were more than forty in number. His earliest significant publication was to demonstrate that children receiving milk from herds of cattle infected with contagious abortion gave evidence of becoming infected with the organism. This was probably the earliest work on the demonstration of the occurrence of undulant fever in man.

His basic interest was the physical chemistry of bacteria which was the concern of many of his papers. He was the first to demonstrate that the form of bacterial growth and cultures was not a character of the organ, but of the relationship of the organ to the medium in which they were growing. He studied the effect of high pressure on microbes and showed that they could be exploded by realeasing them suddenly from high pressure. A number of his scientific studies had to do with the effect of surface tension depressants on bacterial growth and toxin formation. He became especially interested in immunizing against diphtheria and scarlet fever and was the first to effect a method of protecting against these diseases by active immunization with detoxified bacterial toxins. During his years of research he carried out numerous investigations on the bacteriology of lobar pneumonia and was the first to develop an active anti-pneumococcus serum made from rabbits.

At the time of his death, his active investigations concerned the nature of post pneumonic encephalitis and had developed evidence that this was due to abnormal blood clotting associated with the recovery processes.

E. J. Bell

CLIFFORD G. SALT

Dr. Clifford G. Salt, Minneapolis, died February 13, 1947, at the Swedish Hospital, following a prolonged illness. He was sixty-five years of age.

Dr. Salt was a graduate of the University of Ohio and received his medical degree from the University of Minnesota in 1921. He was a member of the Hennepin County Medical Society, the Minnesota State and American Medical Associations. He is survived by his widow, three sons, Terry, John and Thomas, and a daughter, Celia, all of Minneapolis.

Peripheral Arterial Embolism

(Continued from Page 441)

Dr. Borg, in closing: Dr. Kamman's question has been answered, I think. I would simply state that a great number of emboli in the upper extremity require no surgical treatment. However, the last two cases which I had the opportunity of seeing had upper extremity emboli. One patient had numerous embolic phenomena. He called me as soon as his pain came on in the hand. I recognized what had happened and found he had a hand in which no radial pulsation could be felt. I gave him intravenous papaverine and inside of half an hour the color returned in the hand and the numbness disappeared. I do think we cannot regard all upper extremity emboli as innocuous.

The meeting adjourned.

Of General Interest

At an annual reunion dinner on February 25, Dr. R. O. Quello, Minneapolis, was elected president of the Twin City St. Olaf Club.

* * *

Dr. H. R. Butt, Rochester, discussed "Hepatitis" at a meeting of the Woodbury County Medical Society in Sioux City, Iowa, on February 20.

* * *

Dr. L. E. Prickman, Rochester, spoke on "Brucellosis" at a meeting of the West Concord Farm Bureau held in West Concord on March 6.

* * *

At a meeting of the Sedgwick County Medical Society, Wichita, Kansas, early in March, Dr. B. E. Hall, Rochester, presented a paper entitled "Radioactive Phosphorus Therapy."

* * *

Dr. H. A. Roust, Montevideo, after seventeen years in the same office building, has moved to the Bauman Building in Montevideo, where he has opened a six-room office.

* * *

Dr. Thomas Lowry, Minneapolis, has announced the association of Dr. Herbert F. R. Plass in the practice of internal medicine, with offices at 629 Medical Arts Building.

* * *

Dr. Frank E. Mork, Anoka, has been elected vice president of the St. Andrew's Hospital staff in Minneapolis, thereby becoming a member of the Executive Board governing the hospital.

* * *

Dr. Ralph L. Estrem has reopened his medical practice in Fergus Falls. Dr. and Mrs. Estrem and their son recently returned from Panama where Dr. Estrem was stationed while in the army.

* * *

At a postgraduate refresher course at the University of Kansas School of Medicine on March 10, Dr. R. D. Pruitt, Rochester, spoke on "Treatment of Acute Myocardial Infarcation" and "The Precordial Electrocardiogram."

* * *

Carrying out a long-contemplated plan, Dr. M. I. Hauge, Clarkfield, has moved his offices from the lower floor of the Clarkfield Hospital to a new suite in a more centrally located office building.

* * *

"Total Gastrectomy with Esophagoduodenal Anastomosis" was the subject of a talk by Dr. J. T. Priestley, Rochester, at a meeting of the Central Surgical Association held in Chicago in February.

* * *

Dr. John F. Madden, Saint Paul, addressed the Polk County Medical Society at Frederic, Wisconsin, on February 20, speaking on "The Treatment of Common Skin Diseases."

* * *

Dr. Benedik Melby, Blooming Prairie, was married to Miss Julia Hendrickson of that city on March 3. Shortly after the ceremony the couple left for Chicago where they planned to spend several days.

* * *

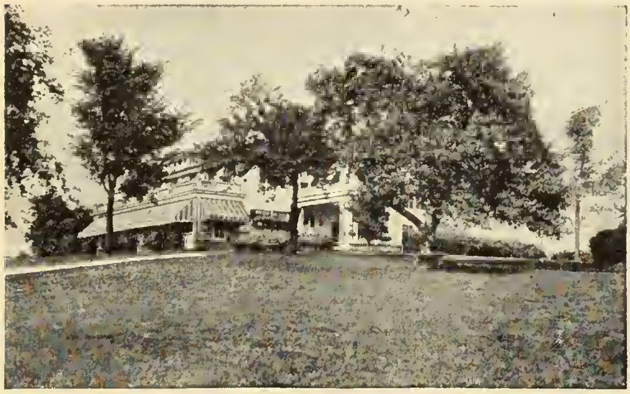
On February 28, Dr. Wilford F. Widen, Minneapolis, gave a talk on "The Game of Life" at the annual Fathers' and Sons' banquet sponsored by the Brotherhood of Ebenezer Lutheran Church in Minneapolis.

* * *

At a meeting of the Minnesota Occupational Therapy Association in Minneapolis on February 22, Dr. E. C. Elkins, Rochester, presented a paper and a motion picture on "Physical Rehabilitation of the Paraplegic."

* * *

During March, Dr. J. A. Bargen, Rochester, traveled to Buneos Aires, Argentina, to participate in a National Medical Convention. On the way he stopped to deliver addresses at meetings of the Medical Society of Puerto Rico at San Juan, Puerto Rico, and the Assembly of Medicine at Rio de Janerio and São Paulo, Brazil.



The Mary E. Pogue School

Complete facilities for training Retarded and Epileptic children educationally and socially. Pupils per teacher strictly limited. Excellent educational, physical and occupational therapy programs.

Recreational facilities include riding, group games, selected movies under competent supervision of skilled personnel.

Among recent lecturers at the Center for Continuation Study at the University of Minnesota have been Dr. J. D. Camp, Rochester, who spoke on "Malacic Diseases of Bone," and Dr. J. M. Waugh, Rochester, who discussed "Vaginal Plastic Operations" and "Vaginal Hysterectomy and Anticoagulant Therapy."

* * *

Pequot Lakes obtained a new physician when Dr. James E. Fearing, formerly of Virginia, became associated with Dr. T. E. Eyres early in March. When Dr. Eyres leaves in June to take postgraduate work at the Cook County Hospital in Chicago, Dr. Fearing will take over the practice.

* * *

Five of the Minnesota surgeons who participated in a sectional meeting of the American College of Surgeons, held in Omaha on March 14 and 15, were Drs. Frederick G. Kolouch, John L. McKelvey and Edward T. Evans, Minneapolis, and Drs. John S. Lundy and Edgar Allen, Rochester.

* * *

Stressing the advances that medicine is making in determining the cause of cancer, Dr. R. W. Kearney, Mankato, discussed progress in medicine at a dinner meeting of the Mankato Business and Professional Women's Club on February 18. The meeting was held in observance of the club's annual health program month.

was attended by Dr. Raymond N. Bieter, head of the Department of Pharmacology in the University of Minnesota Medical School. The conference was sponsored by the National Foundation for Infantile Paralysis.

* * *

Dr. A. H. Wolf, Harmony, recently sold his office equipment and medical practice to Dr. Carl G. Nelson, formerly of Minneapolis. Dr. Nelson, who has begun his practice in Harmony, graduated from medical school in 1942 and later spent almost three years in the army, two years of which were in overseas service.

* * *

The University of Minnesota regents at their monthly meeting on February 14 named Dr. William B. Tucker as a clinical associate professor of medicine. Dr. Tucker, who is chief of the tuberculosis service at the Veterans Hospital in Minneapolis, will serve part time at the University.

* * *

Dr. J. Hartman, in charge of the Soudan Hospital for the past year and a half, has resigned his position and moved to Portland, Oregon, to enter private practice. The hospital, owned by the Lenont-Peterson Clinic of Virginia, has been taken over by Dr. T. P. Mollers of Mountain Iron.

* * *

Dr. H. Waltman Walters, Rochester, has been appointed to the National Advisory Cancer Council of the United States Public Health Service. Dr. Walters, who graduated from Dartmouth College and did graduate work in surgery at the University of Minnesota, is a surgeon at the Mayo Clinic and professor of surgery in the Mayo Foundation.

* * *

Certification to the American Board of Internal Medicine has been awarded Dr. Randall Derifield, Hibbing, it was announced March 1.

Dr. Derifield, a staff member of the Mesaba Clinic, was a lieutenant colonel in the army during the war and served overseas for thirty months, the greater part of which time was spent in New Caledonia.

* * *

Attended by more than 200 Izaak Walton members from throughout the state, a testimonial dinner was held in Rochester on February 20 to honor Dr. M. M. Hargraves, Rochester, the new state president of the organization. Past and present state and national officers of the Izaak Walton League were included in the group which gathered to salute Dr. Hargraves.

* * *

In Stillwater, Dr. R. J. Josewski and his staff are now established in a new suite of offices on South Main Street. Decorated and furnished with an emphasis on patient comfort, the office suite consists of a reception room, children's room, examination and consultation rooms, as well as a modern x-ray room and darkroom.

* * *

In charge of a veterans' psychiatric service, recently inaugurated in Minneapolis by the Hennepin County Red Cross, is Dr. Eric K. Clarke, assisted by Dr. Stanley G. Law and Dr. William Fleeson of the Minnesota Psychiatric Institute. The psychiatric service, located in offices at 1111 Nicollet Avenue, Minneapolis, is available to veterans and members of their families.

* * *

A new staff member of the Worthington Clinic is Dr. John Stam, formerly of Minneapolis, who began practice in Worthington on March 17.

Dr. Stam, a graduate of the University of Illinois Medical School, interned at Cook County Hospital, Chicago, and was a resident in pediatrics at Northwestern Hospital, Minneapolis. For a time he practiced general medicine at La Grange, Illinois.

* * *

Dr. Richard H. Picha, recently discharged from the army, plans to enlarge the St. Louis Park office which he shares with Dr. A. C. Stahr, and to continue his Hopkins practice. A graduate of the University of Minnesota, Dr. Picha has practiced in St. Louis Park for thirteen years. While in the army, he worked in anesthesia and general surgery at hospitals in Michigan, Indiana and Illinois.

* * *

The Glenwood Clinic, a twenty-three room, air-conditioned structure erected by Dr. M. B. Dahle, Glenwood, was officially opened on March 15. Occupied by Dr. Dahle and Dr. P. A. Swedenburg, the new clinic building contains a ward, an operating room, x-ray laboratory, physiotherapy and eye-ear-nose-throat departments, three suites of offices, a four-room dental suite, and a large reception room.

Dr. Joseph L. Arko, Hibbing, attended a course in ophthalmology from February 17 to 21 at the Center for Continuation Study at the University of Minnesota.

* * *

Among those from the Duluth area who attended the meeting of officers of county medical societies of the Minnesota State Medical Association, held in Saint Paul on March 1, were Dr. D. W. Wheeler, president, and Dr. Elizabeth Bagley, secretary-treasurer, of the St. Louis County Medical Society.

* * *

Dr. Francis W. Lynch, Saint Paul, clinical associate professor of dermatology at the University of Minnesota, was guest speaker at a meeting of the Northwest District Medical Society held on February 27 in Minot, North Dakota. Speaking on epidemic ringworm of the scalp, Dr. Lynch described how the disease has been treated in school children in Saint Paul during the past two years.

* * *

In an exchange of cigars with Dr. Charles W. Brown, Minneapolis, on February 26, Dr. William A. O'Brien, director of postgraduate medicine at the University of Minnesota, thought he had developed diplopia.

Dr. O'Brien was passing out cigars to celebrate the arrival of a baby daughter, his sixth child. Dr. Brown for the same reason was passing out cigars, only his came in doubles. Mrs. Brown had given birth to twins.

* * *

With the recent reappointment by Governor Youngdahl of two members whose terms expired January 1, 1947, and the appointment of one new member, the State Board of Health now consists of Drs. T. B. Magath, Ruth E. Boynton, F. W. Behmler, and E. S. Platou; W. L. Webb, D.D.S.; Gustav Bachman, Pharm.D.; F. E. Bass, C.E.; L. M. Thompson; and M. Sidney Hedeen, D.O., succeeding Dr. A. G. Schulze, who has resigned.

* * *

Dr. C. C. Burlingame, former assistant superintendent of the Fergus Falls State Hospital, is now head of a large neurological clinic in the East, with twenty-one physicians on his staff, and with offices in New York, Boston, and New Haven, Connecticut.

While in Fergus Falls, Dr. Burlingame attracted national attention for his work in wiping out typhoid fever among the patients at the state hospital. During World War II he was a member of General Marshall's staff. He has recently completed a medical survey in France, Germany and England.

* * *

Dr. Joseph B. Gaida, St. Cloud, has announced the association of Dr. John E. Conway as a specialist in eye, ear, nose and throat diseases.

Dr. Conway, a graduate of the University of Wisconsin Medical School in 1940, interned at Ancker Hospital, Saint Paul, and took postgraduate training in eye, ear, nose and throat diseases at the University of Minnesota. He was assistant resident in 1941-42, and chief resident in 1942-43, in the Eye, Ear, Nose and Throat Department of Ancker Hospital. While in the army, he was chief of the Eye, Ear, Nose and Throat Departments of army hospitals at Herrington and Topeka, Kansas.

* * *

Dr. Fred J. Pratt, Jr., who recently returned from the East where he had been doing postgraduate work since his release from the army, is now associated with his father, Dr. F. J. Pratt, Sr., and with Dr. G. M. Koepcke at 801 Physicians and Surgeons Building, Minneapolis.

Dr. Pratt, a graduate of the University of Arkansas Medical School, interned at Minneapolis General Hospital and had a year of residency there in eye, ear, nose and throat diseases. While in the army, he was stationed at the Nautilus Veterans Hospital, Miami Beach, Florida, in charge of the Eye, Ear, Nose and Throat Department.

* * *

Sponsored by Sigma Xi, scientific fraternity, Dr. Gaylord W. Anderson, director of the School of Public Health at the University of Minnesota, discussed advances in medicine during World War II, at a special lecture on February 25 in Northrop Memorial Auditorium at the University. During the war Dr. Anderson was director of the Division of Medical Intelligence in the office of the Surgeon General.

Earlier in the month Dr. Anderson spoke to the Faculty Women's Club at the University on the type of work done by his division during the war, work that included the compilation of climatic, health and sanitary evidence from every part of the world.

A pioneer physician of the border country, Dr. Robert Hugh Monahan, Sr., International Falls, has retired after forty years of active practice.

Dr. Monahan, a graduate of Hamline University Medical School and the University of Minnesota, practiced in International Falls from 1909 to 1917 and again from 1940 to 1947. He enlisted in the army in 1917 and, while stationed in England, studied orthopedics under Sir Robert Jones, one of the outstanding orthopedic surgeons of the time. Following the war, Dr. Monahan practiced in Minneapolis and was a staff member of St. Barnabus Hospital for twenty years.

Returning to International Falls in 1940, he served on the Selective Service examining board in addition to maintaining a private practice and helping to manage the local hospital. Recently, his son, Dr. R. H. Monahan, Jr., after service in World War II, returned to the city to resume medical practice.

Dr. Monahan, Sr., began his retirement in late January by leaving for California for the remainder of the winter.

The U. S. Civil Service Commission has announced an examination for filling Medical Officer positions.

These positions are located in various Federal agencies, in Washington, D. C.; in the U. S. Public Health Service and the Indian Service, throughout the United States; and in the Panama Canal Service, in the Panama Canal Zone. Salaries range from $4,149 to $5,905 a year, with higher salary rates for the Canal Zone positions. No written test will be given for these positions. To qualify, all applicants must be graduates of a medical school of recognized standing and must also meet other requirements which include experience and training in the field of medicine. The age limits are 45 years for Panama Canal Zone positions and 62 years for other positions. These age limits are waived for persons entitled to veteran preference (up to the age of 62 for the Panama Canal Service and without limitation for other agencies).

Interested persons may secure information and application forms from most first- and second-class post offices, from Civil Service regional offices, or from the U. S. Civil Service Commission, Washington 25, D. C. Applications must be filed not later than April 22, 1947.

HOSPITAL NEWS

New finance manager of the Northern Minnesota Hospital, International Falls, is F. R. Willey, formerly of Minneapolis, it was announced March 1. As part of a new policy, patients now entering the hospital will be required to make an advance payment of one week's expenses unless they hold acceptable hospitalization insurance.

* * *

The third appointment within thirteen months of a new head for the Minneapolis Veterans Hospital, Dr. Erwin J. Rose has been named manager of the hospital to succeed Colonel Harry E. Caldwell.

In answer to the charges made recently by the Veterans of Foreign Wars and the Disabled American Veterans organizations, that the tuberculosis wards at the hospital were mismanaged, investigators from the headquarters of the Veterans Administration announced that patients in the Minneapolis hospital receive better care than anywhere else in the country.

The Veterans Administration stated that Colonel Caldwell would be assigned to another post, and that Dr. Rose's appointment had been under consideration for several months.

* * *

W. Dayton Shields has been appointed administrator of Asbury Hospital, Minneapolis, to replace Lydia A. Miller who retired on March 1 after nineteen years as superintendent.

Mr. Shields, a graduate of the University of Min-

nesota Business School, formerly was in the administrative office of Swedish Hospital, Minneapolis. For three years during the war he was associated with an army general hospital unit, and following the war, he took a course in hospital administration at Northwestern University.

* * *

On February 28 Northwestern Hospital, Minneapolis, opened a new laboratory which contains one of the most modern blood transfusion services in the country. Housed in a new wing of the building, the laboratory is divided into sections for bacteriology, chemistry, hematology, tissue pathology, and blood processing and storage. As part of the equipment for the blood bank, the laboratory has a precipatron, a type of air-conditioning unit, which removes dust and bacteria from the rooms in which blood and plasma are processed.

In charge of the laboratory is Dr. Sheldon H. Stuurmans, pathologist for Northwestern Hospital.

* * *

From the hospital planning committee in Blue Earth has come word that excellent progress is being made towards the erection of a community memorial hospital. At present, funds for construction of the hospital total over $90,000. Since January 1 about $20,000 in cash payments on new and old pledges have been added.

In February committee members conferred with Dr. Viktor O. Wilson, of the Minnesota State Department of Health, in regard to design and methods of management of the proposed hospital. Members of the committee include Homer Enterline, Elmore; Clifford Kittelson, Frost; Walter Schwen and John Frundt, Blue Earth.

* * *

In Westbrook a drive is in progress to collect funds for the erection of a hospital to be known as the Dr. Henry Schmidt Memorial Hospital.

* * *

An open meeting was held in Paderewski Hall, Browerville, on February 27, to discuss possibilities of using Federal funds under the Hill-Burton Act to improve hospitalization facilities in Todd County. Principal speakers at the meeting were Dr. Viktor O. Wilson, representative of the State Department of Health and head of the Hospital Licensing Division, in Minnesota, and K. A. Kirkpatrick, Minnesota Farm Bureau hospitalization director.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

THE COMPLEAT PEDIATRICIAN. Practical, diagnostic, Therapeutic and Preventive Pediatrics. Wilburt C. Davison, M.A., D.Sc., M.D., Professor of Pediatrics, Duke University, etc. 5th ed. Price, $3.75 with order; $4.00 on credit. Durham, N. C.: Duke University Press, 1946.

The Compleat Pediatrician, now in its fifth edition, has become a *sine qua non* among all those who wrestle with the innumerable problems and diagnostic difficulties of children.

The reviewer has been familiar with this book for many years, and it would be about the last book he could spare.

When the pediatrician runs into a peculiar situation, when nothing seems to add up exactly right, it will be seldom indeed that he will not get a lead of some kind from this book that will set him on the right path. It is a veritable encyclopedia of information, well sifted, condensed, practical and comprehensive. It is a book which every pediatrician will want on his desk and which he will consult first in every pediatric quandary.

C. H. Schroeder, M.D.

MODERN MANAGEMENT in Clinical Medicine. Frederick K. Albrecht, M.D. 1238 pages Illus. Price $10.00. Baltimore: Williams & Wilkins Company, 1946.

This book is a compilation of our present knowledge of modern medicine, written in a manner the average doctor enjoys. The author must have devoted a tremendous amount of effort and time in collecting the valuable information presented. Each subject is discussed thoroughly, and still the style is not verbose. An example of this is the chapter dealing with the subject of endocrinopathies.

The use and rationale of the newer drugs is discussed fully. Illustrations throughout are very helpful.

Although the author intended this book for the doctor's office, it would be a very practical addition to the library of the intern, general practitioner or clinician in any specialty.

Joseph M. Ryan, M.D.

A BLIND HOG'S ACORNS. Cary P. McCord, 311 pages. Price, $2.75. Chicago; Cloud, Inc., 1946.

Taking the title of his book from a remark made in his youth that "even a blind hog gets an acorn once in a while," the author shows by a series of interesting anecedotes that a medical man with his wits about him can solve many baffling problems in an industrial practice.

EVANSVILLE IND U S A

COUNCIL-ACCEPTED

AMIGEN

for parenteral administration of amino acids

The function of Amigen and Protolysate is to supply the amino acids essential for nutrition. Both can be given in place of protein when protein cannot be eaten or digested, or in addition to protein when the protein intake is insufficient. Administered in adequate amounts, they prevent wastage of protein, restore previous losses, or build up new body protein.

COUNCIL-ACCEPTED

PROTOLYSATE

for oral and tube feeding of amino acids

1 LB. NET (454 GM.)
MEADS
PROTOLYSATE
For Oral Administration
A dry enzymic digest of casein containing amino acids and polypeptides, useful as a source of readily absorbed food nitrogen when given orally or by tube. Protolysate is designed for administration in cases requiring predigested protein. The mode of administration and the amount to be given should be prescribed by the physician.
MEAD JOHNSON & CO.
EVANSVILLE, IND., U S A

1 lb. cans at drug stores

Like Amigen, Protolysate is an enzymic digest of casein and consists of amino acids and polypeptides. Like Amigen, Protolysate supplies the nitrogen essential for maintenance, repair and growth.

Unlike Amigen, which may be employed both orally and parenterally, Protolysate is designed only for oral use.

MEAD JOHNSON & CO., EVANSVILLE 21, INDIANA

There is no shortage now of AMIGEN for parenteral use. There is no shortage now of PROTOLYSATE for oral use.

The dark field spotlights the slender, nimble undulating form of Treponema pallidum to establish a diagnosis of syphilis. The prognosis may be dark if the patient fails to receive adequate therapy.

natural equilibrium

Amniotin, a complex of *truly natural* estrogens, has been helping physicians level the vicissitudes of the menopause for over seventeen years. A wide range of forms and potencies permits notable flexibility and *precision* in dosage.

The objective of using "the minimum dosage at the longest possible intervals compatible with the control of symptoms"[1] is readily attained. Once symptoms are *controlled parenterally,* the patient may be easily *maintained orally* on a gradually reduced dosage. Amniotin is highly purified, standardized in International Units.

When Nitrogen Balance Must Be Restored

In the correction of protein insufficiency, or in the maintenance of nitrogen balance, accumulating evidence substantiates the dictum that hydrolyzed protein substances should be employed *only* when oral feeding of protein foods is impossible or not feasible.

It has been shown experimentally[1] when hydrolysates of protein are injected at two different rates (1.0 and 1.5 mg. of nitrogen per Kg. of body weight per minute), the more rapid injection rate results in a higher excretion of both free amino acids and peptides. The authors ventured that even in the presence of a definite demand for protein replenishment, nitrogen excretion is mainly controlled by the kidney threshold.

In a recent survey, Ravdin[2] stated that "When oral feeding is used, whole foodstuffs should be given. There is no beneficence in feeding protein hydrolysates unless there is evidence of faulty digestion. Feeding of mixtures of polypeptides and amino acids may result in an absorption rate of amino acids which is more rapid than can be resynthesized by the liver, especially when the function of this organ is not normal."

When protein foods are ingested, the contained amino acids are released slowly and in a sustained manner during the course of the digestive processes. The absorptive capacity of the intestinal mucosa is not overtaxed, and maximal amino acid utilization is made possible without urinary loss.

As a source of protein, meat ranks high among the foods of man. It is 96 to 98 per cent digestible, and its protein is biologically adequate, capable of satisfying every protein need of the organism.

chemically similar to natural estrogens

ESTINYL (ethinyl estradiol) is "chemically similar to natural estrogen."[1] It is more active *orally* than any other synthetic or natural estrogen known today. ESTINYL is the first estradiol preparation that is efficacious by mouth in really minute amounts. It provides the economy inherent in low dosage. Five-hundredths of a milligram daily is sufficient to relieve the average menopausal patient. ESTINYL, closely allied to the primary follicular hormone, does more than mitigate vasomotor symptoms. ESTINYL quickly relieves the common nervous manifestations and bodily fatigue, and replaces them with a sense of emotional and physical fitness.

ESTINYL

tablets

Average menopausal symptoms: One 0.05 mg. ESTINYL Tablet daily. Severe menopausal symptoms: Two or three 0.05 mg. ESTINYL Tablets daily. Many patients may be maintained in comfort with 0.02 mg. ESTINYL Tablet daily after initial control of estrogen deficiency.

Packaging: ESTINYL TABLETS of 0.05 mg.—pink, coated tablets and 0.02 mg.—buff, coated tablets, bottles of 100, 250 and 1,000.

"accuse me, please"

- A Doctor without broad malpractice insurance (*and preventive, confidential counsel and service!*) is asking for trouble.
- Disgruntled patients *ac*cuse, but rarely *ex*cuse. And merely having liability insurance is small comfort to a doctor whose reputation is shattered in a lawsuit.
- We, too, pay judgments. But, as the company devoting its resources *exclusively* to the protection of doctors, we direct most of our efforts to the *prevention* of malpractice lawsuits.
- Our confidential service, backed by the world's largest legal staff of malpractice experts, keeps most claims from reaching court at all. Failing that, we fight through the court of last resort with additional legal counsel whom *you* may help choose.
- *All* costs of preventing or fighting such lawsuits are paid by us. Annual premium: the price of 2 or 3 shirts.

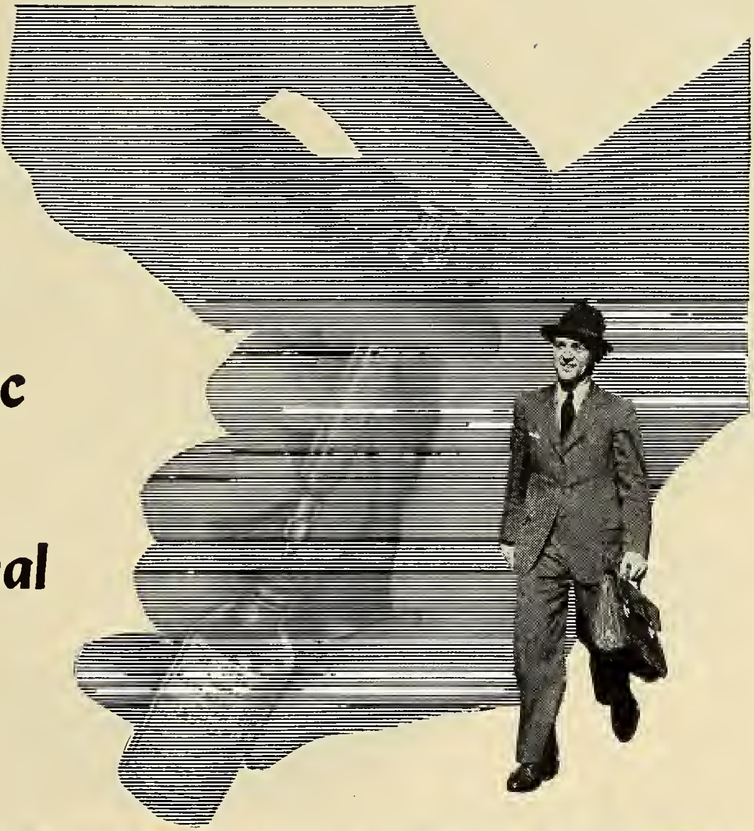
to convert the diabetic into a more normal person



"The ideal in therapy...is to convert the diabetic into a normal person."[1] While certain restrictions must always be imposed, many patients can be controlled through diet alone so as to dislocate their normal habits as little as possible. In those cases where insulin therapy is also required, control may often be attained with but *one daily injection* of 'Wellcome' Globin Insulin with Zinc. Its intermediate action is adaptable to the needs of most mild and many moderately severe cases and adequate control can usually be achieved in three clear-cut steps:

1. *Stabilize the patient* as well as possible on a diet of the desired caloric content. Give a single dose of 15 or 20 units of 'Wellcome' Globin Insulin 30 minutes or more before breakfast.

2. *Adjustment to 24-hour control:* Gradually adjust the Globin Insulin dosage to provide 24-hour control as evidenced by a fasting blood sugar level of less than 150 mgm. or sugar-free urine in the fasting sample.

3. *Adjustment of diet:* Simultaneously adjust the carbohydrate distribution of the diet to balance insulin activity. Initially this may be 2/10 (breakfast), 4/10 (lunch), and 4/10 (supper). Any tendency toward mid-afternoon hypoglycemia may usually be offset by giving 10 to 20 grams of carbohydrate between 3 and 4 p.m. The final adjustment of carbohydrate distribution may be based on fractional urinalyses.

Systematic attention to these details will make possible adequate control of most mild and many moderately severe cases of diabetes with a *single daily injection of 'Wellcome' Globin Insulin with Zinc.*

'Wellcome' Globin Insulin with Zinc is a clear solution, comparable to regular insulin in its freedom from allergenic properties. Available in 40 and 80 units per cc., vials of 10 cc. Accepted by the Council on Pharmacy and Chemistry, American Medical Association. Developed in The Wellcome Research Laboratories, Tuckahoe, New York. U.S. Patent No. 2,161,198. DO
YOU
KNOW
WHAT
THESE
SYMBOLS
STAND
FOR ?

From man's earliest ages, the serpent is found in religious, medical and art symbolism. It enjoys many and varied connotations, some good, some evil. This particular serpent, with its tail in its mouth, symbolizes Eternity—time without beginning and without end.

The modern symbol of superior pharmacal service is the familiar Rexall sign. More than 10,000 independent, reliable drug stores throughout the country display this symbol. It means that prescriptions filled there will be compounded with the highest pharmacal skill, from pure, potent drugs. All Rexall drugs are laboratory-tested under the Rexall control system.

to combat

the depression of

chronic organic disease Many patients with chronic organic disease—arthritis or asthma, for example—sink into a persistent depression characterized by discouragement, or even despair. Unless effectively combated, this depression may handicap management of the basic disorder and intensify its symptoms.

By restoring optimism and interest in useful living, Benzedrine Sulfate frequently helps to overcome prolonged depression accompanying chronic illness. Obviously, in such cases, careful observation of the patient is desirable; and the physician will distinguish between the casual case of low spirits and a true mental depression.

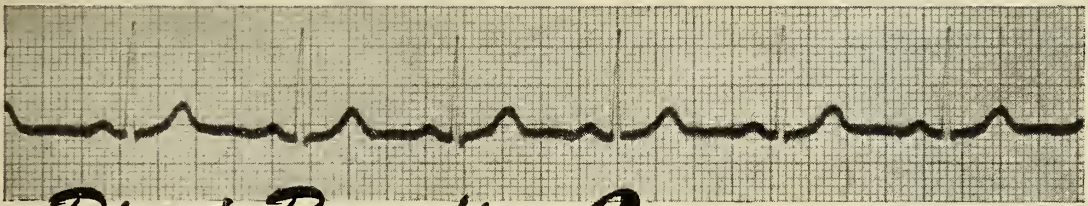
Modern ELECTRO-CARDIOGRAPHY



Direct-Recording ***Cardiotron***

Portable, rugged, electrically operated without batteries. Cardiotron is available with or without stand.

The first successful *Direct-Recording* Electrocardiograph...

With more than 1200 now in use throughout the world, the Cardiotron has established the principle of instantaneous recording in general clinical electro-cardiography.

The Cardiotron is fast, accurate and sensitive. It makes an *immediate* black and white cardiogram—on *permanent* chart paper. It is free from skin resistance errors. It reveals more information than any other electrocardiograph instrument.

IMPORTANT: Factory-supervised installation and service are available in most parts of the world. Good deliveries are scheduled. Cardiotron is sensibly priced.

MINIMIZES GASTROINTESTINAL DISTRESS

Gastrointestinal distress attributable to the presence in the intestinal tract of excessive amounts of readily fermentable sugars can be minimized by specifying CARTOSE* as the mixed carbohydrate to be used in modifying milk for infant feeding formulas.

CARTOSE supplies balanced proportions of nonfermentable dextrins in association with maltose and dextrose, thus providing spaced absorption.

Its content of dextrins favors the development of a preponderant beneficial acidophilic intestinal flora.

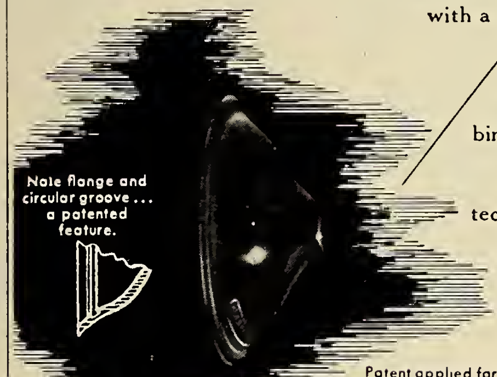
Presenting...

PLASTISHIELDS

A new technique for postpartum breast care.

PLASTISHIELDS are transparent shields, formed to receive the breast. They have an extruded central portion to *loosely* receive the nipple. Made from a plastic which does not react with skin or milk, they are moulded and hand-finished to assure perfect smoothness and comfort. A flange around the circumference with a circular groove in its inner surface forms a suction to hold the shield firmly to the breast. Used with either a hospital binder or brassiere. The method is adaptable as a simple standard routine technique, usable in both hospital and home.



Patent applied for U S Patent Office

ADVANTAGES:

1. Prevents irritation of nipples by clothing.
2. Protects nipples and breasts from infection.
3. Reduces nursing discomfort.
4. Simplifies nipple care.
5. Eliminates use of ointments, gauze, etc.
6. Increases patient's comfort.
7. Easily sterilized by patient, after each nursing, thus saving nurse's time.
8. Shortens latent period of nursing.
9. Minimizes milk seepage and soiling of clothing.
10. Corrects certain cases of flat or partially inverted nipples.
11. Not affected by ordinary antiseptics.

Now being successfully used in many hospitals throughout the Northwest for routine postpartum breast care.

OBSTETRICAL SUPERVISORS SAY:

"Convinced of their superiority over other methods of breast care."

"Its use has improved and simplified our nursing care . . . protects nipples from contamination . . . an added source of comfort to nursing mothers."

"Excellent reception by both patients and nurses . . . happy to recommend continued use at our hospital."

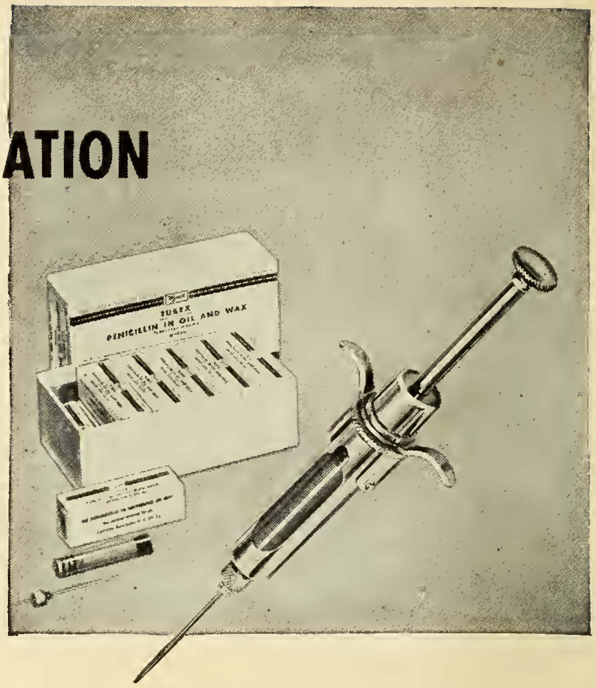
PENICILLIN ADMINISTRATION

is safe, simple, and fast with TUBEX®



Before injecting aspirate to insure that needle is not in a blood vessel.

- Designed for immediate injection — no transfer from ampul to syringe.
- Administration is rapid—300,000 units injected in less than 30 seconds.
- Tubex has a special safety feature—by aspirating, it is easy to make certain that a blood vessel has not been entered.
- Positive plunger of the syringe eliminates awkward administration.

Prolonged therapeutic blood levels (12 to 24 hours) have frequently been observed after a single injection of 300,000 units. Nearly all cases of acute gonorrhea are cleared up by a single injection. Other susceptible coccal infections respond to one or two injections per day.

Available in 1 cc. Tubex, 300,000 units of penicillin calcium, with Tubex needle (20 gauge, 1½ inch). The Tubex syringe is supplied separately.

Tubex syringes and needles, developed and produced by J. Bishop & Co., are used exclusively by Wyeth Incorporated.

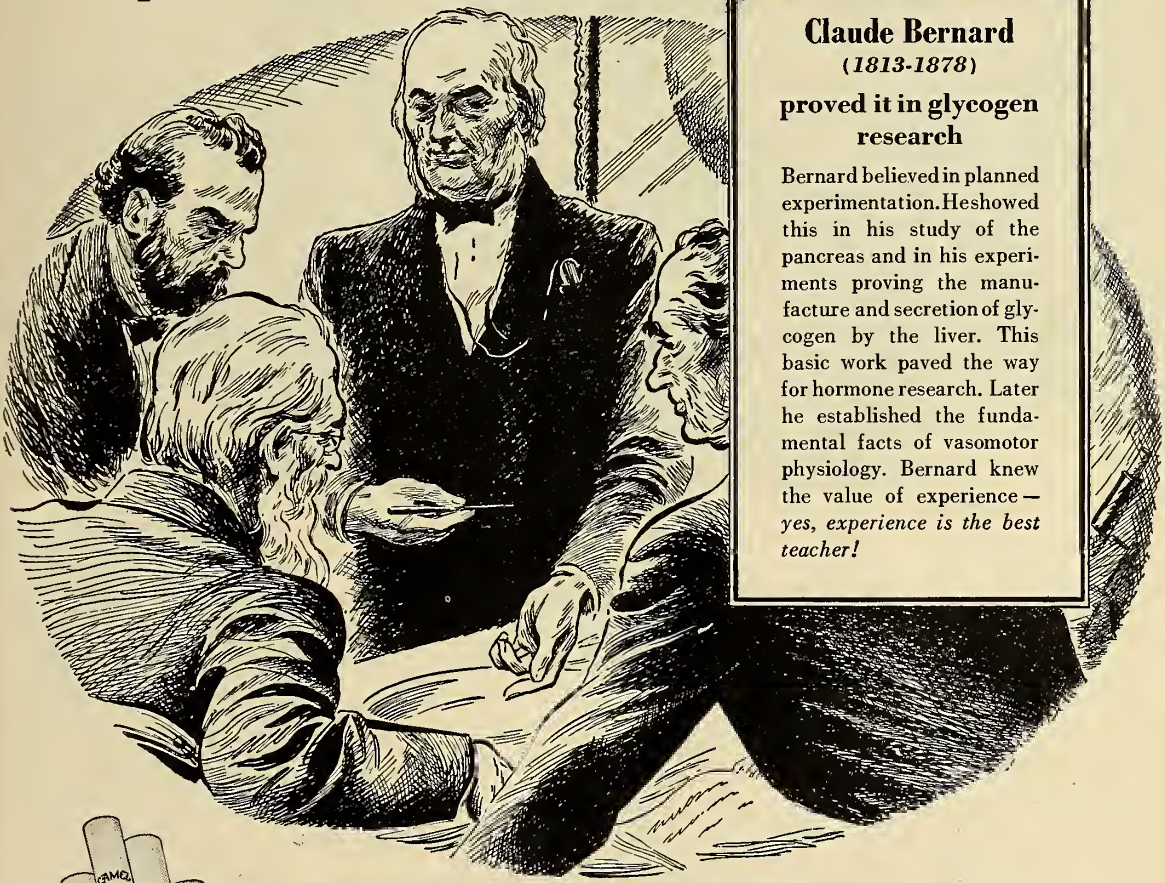
Experience is the Best Teacher



Claude Bernard
(*1813-1878*)

proved it in glycogen research

Bernard believed in planned experimentation. He showed this in his study of the pancreas and in his experiments proving the manufacture and secretion of glycogen by the liver. This basic work paved the way for hormone research. Later he established the fundamental facts of vasomotor physiology. Bernard knew the value of experience — *yes, experience is the best teacher!*

CAMEL
CHOICE QUALITY
TURKISH & DOMESTIC BLEND CIGARETTES

Yes, and experience is the best teacher in smoking too!

THAT wartime cigarette shortage was a real experience to smokers. Millions of people smoked more different brands than they would normally try in a lifetime. And out of the comparisons of that experience so many more smokers came to prefer Camels that today more people are smoking Camels than ever before.

We don't tamper with Camel quality. Only choice tobaccos, properly aged, and blended in the time-honored Camel way, are used in Camels.

According to a recent Nationwide survey:

MORE DOCTORS SMOKE CAMELS

than any other cigarette

R. J. Reynolds Tobacco Co., Winston-Salem, N. C.

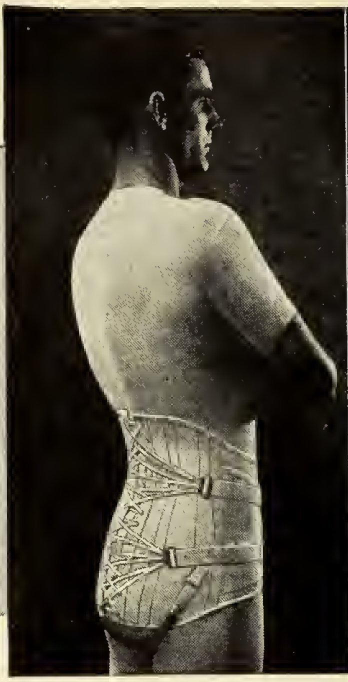


FIGURE 1—Patient—thin type of build with beginning faulty body mechanics. The Camp adjustment provides a more stable pelvis, allowing patient to "draw in" the abdominal muscles thus gradually acquiring a gentle lumbar curve.

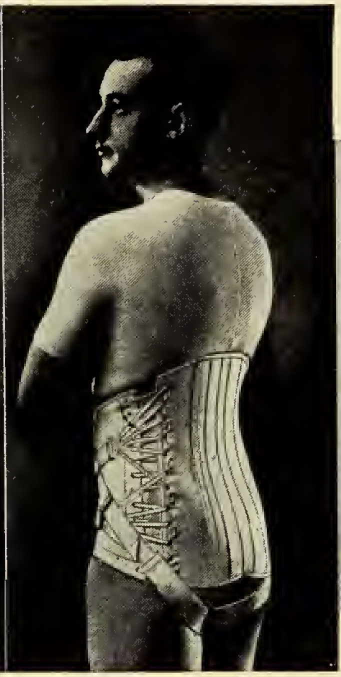

FIGURE 2—Patient—intermediate type of build. Strain of lumbosacral joint predisposes to other strains. For protection of the joints in the lumbar region from recurrent strain and also as an aid in relieving the pain of acute conditions, Camp lumbosacral supports have proved effective.

In the Conservative Treatment of

The Lumbosacral and Lower Lumbar Regions

CAMP SUPPORTS offer advantages

•••Give firm support to the low back; the support is easily intensified by re-inforcement with pliable steels or the Camp Spinal Brace.

•••Afford a more stable pelvis to receive the superincumbent load.

•••Allow freedom for contraction of abdominal muscles under the support in instances of increased lumbar curve (fig. 1).

•••Are removed easily for prescribed exercises and other physical procedures prescribed by physiatrist or physician.

"the events of all past days"

"A person's nutritional status today depends on the events of all past days."[1] Slight deficiencies should not be ignored "as if they were without effect," for "partially, indeed slightly deficient diets eaten regularly and periodically over many years have their consequences."[1] Such nutritional delinquency often takes its greatest toll under the stress of illness, surgery, pregnancy, lactation, or accident. For depleted tissues, Upjohn vitamins provide a wide range of dosage forms for therapy or supplementation, in preparations adapted to oral and parenteral administration in the practice of medicine and surgery.

30 day wonder

The new-born infant is truly a "30-day wonder" taking in his stride the sudden changes birth imposes and adjusting accordingly. The rapid increase in weight is, alone, a feat no adult could duplicate. The right start on the right feeding is of vital importance—particularly during the first 30 days when infant mortality is at its highest and when he not only must regain his birthweight *but keep on gaining* if he is to survive.

'Dexin' has proved an excellent "first carbohydrate" because of its high dextrin content. It (1) resists fermentation by the usual intestinal organisms; (2) tends to hold gas formation, distention and diarrhea to a minimum, and (3) promotes the formation of soft, flocculent, easily digested curds.

Simply prepared in hot or cold milk, 'Dexin' brand High Dextrin Carbohydrate provides well-taken and well-retained nourishment. 'Dexin' *does* make a difference. *Literature on request*

PEPTIC ULCERS

A recent conservative estimate places the incidence of peptic ulcer at 5 per cent of the population, or about 6,500,000 persons in the United States.* The great majority of this vast group of patients need a year-in and year-out program of rest, diet and acid neutralization.

Creamalin, the first aluminum hydroxide gel, readily and safely produces sustained reduction in gastric acidity. With Creamalin there is no compensatory reaction by the gastric mucosa, no acid "rebound," and no risk of alkalosis. Through the formation of a protective coating and a mild astringent effect, nonabsorbable Creamalin soothes the irritated gastric mucosa. Thus it rapidly relieves gastric pain and heartburn, and helps in the healing of peptic ulcers as well as in the prevention of ulcer recurrence.

# of G-E Model R-39 X-Ray Units Now in Service!

If you can picture in your mind's eye a two-mile column of R-39 Units, placed end to end, you'll have a good idea of the popularity of this particular model, and the vast amount of diagnostic service it is rendering daily in the offices of specialists, and in clinics and hospitals everywhere.

Why the R-39's great popularity?

1. It is an all-round diagnostic unit, yet is so compactly designed that it can be accommodated in a small floor space.
2. Has ample power (100 ma. and 85 kvp) for general radiographic and fluoroscopic diagnosis.
3. Its unusual flexibility facilitates positioning of the patient vertically, angularly, or horizontally.
4. Its double-focus genuine Coolidge tube serves both over and under the table.
5. The simple-to-operate, refined control system assures a consistently fine quality of work.

You, too, may find the Model R-39 ideally adaptable to your particular needs. Why not investigate, by writing today for complete information. Address Dept. 2616, General Electric X-Ray Corporation, 175 W. Jackson Blvd., Chicago 4, Ill.

Borden's prescription specialties are flexibly adaptable to cope effectively with the sharply increased number of your infant feeding problems.

BIOLAC—a complete infant formula (only vitamin C supplementation needed) for infants deprived of mother's milk.

DRYCO—a powdered, high-protein, low-fat, moderate carbohydrate milk food ideally suited for all formulas.

BETA-LACTOSE—an exceptionally palatable, highly soluble milk sugar for formula modification.

MULL-SOY—a hypo-allergenic emulsified soy food for infants and adults allergic to milk proteins. The 1:1 standard dilution approximates cow's milk in fat, protein, carbohydrate and mineral content.

KLIM -a spray-dried whole milk with soft curd properties essential in infant feeding and special diets. Particularly valuable when availability or safety of fresh milk is uncertain.

Borden prescription products are available at all drug stores. Complete professional information may be obtained on request.

World of new hope in petit mal

One important fact stands out in the rapidly expanding clinical record of Tridione: Thousands of children formerly handicapped in school and play by petit mal, myoclonic or akinetic seizures are finding substantial relief through treatment with Tridione. In one test, Tridione was given to 150 patients who had not received material benefit from other drugs.[11] With Tridione, 33% became seizure free; 30% had a reduction of more than three-fourths of their seizures; 21% were moderately improved; 13% were unchanged, and only 3% became worse. In some cases, the seizures, once stopped, did not return when medication was discontinued. Tridione also has been shown to be beneficial in the control of certain psychomotor epileptic seizures when used in conjunction with other antiepileptic drugs.[12] Wish more information? Just drop a line to Abbott Laboratories, North Chicago, Illinois.

An Appeal to You . . Doctor

SCHOOL OF PSYCHIATRIC NURSING

•

MID-YEAR CLASS will start in June

•

Candidates for the June class should make reservations at once. School and health record must be reviewed and correspondence completed prior to acceptance.

An acute shortage exists in the nursing field. The problem of supplying an adequate number of well-trained nurses to the medical profession has become a difficult one. *Your help in recruiting candidates for training schools is greatly needed.* In your wide acquaintance, you possibly know of many girls who could be interested in becoming a nurse. As a leading citizen of your community you are in a position to assist them in their vocational choice. *A trained nurse is a benefit to both your patient and yourself.* We are prepared to refer the student nurse back to you on completion of her training.

A Career in Nursing Offers:

- **Training in a highly paid profession**
- **A secure position unaffected by economic depression**
- **Work with skilled professional men and women**
- **The best preparation for marriage**

Glenwood Hills Hospitals, beautifully located on the outskirts of Minneapolis, are currently offering to qualified applicants a one year course in the School of Psychiatric Nursing. All phases of the subject are skillfully presented by a capable and experienced faculty. Classroom and laboratory study is combined with an interesting program of actual work on the ward. Regular classes begin in January, June, and September.

Here is an opportunity to attain a useful higher education and still enjoy the beauty of summer to its fullest. Swimming, boating, hiking, and golf are a few of the recreational pastimes available to the student nurse. *Tuition is free.* We will be happy to send full information on request. A postcard is sufficient. Address Miss Margaret Chase, R.N., B.S., *Director, School of Nursing, Glenwood Hills Hospitals.*

- ***Our hospitals must be staffed***
- ***Our sick must be cared for***
- ***Our doctors must have nurses***

PROTEIN AND AMINO ACID THERAPY

ROBERT ELMAN, M.D.
Saint Louis, Missouri

It is only within the past decade or two that the importance of protein intake has become appreciated. In discussing this subject, it will be necessary to consider both protein and its building stones, i.e., amino acids, which normally furnish the medium of exchange between protein in the food and body protein, as well as between various body proteins.

The subject of protein and amino acid therapy has a wider interest than merely one of nutrition inasmuch as many surgical conditions result in a loss of blood and exudate, which are essentially protein-containing fluids. In this sense also, transfusions of blood and plasma, which are also protein-containing solutions, come under consideration in the discussion of protein and amino acid therapy.

General Considerations

The importance of protein may be expressed by a statement attributed to Rubner that "protein contains the magic of life, ever newly created, ever dying." This dynamic view of protein metabolism was prophetic, for it was only in the past decade or two that the same conclusion was reached by Shoenheimer and his co-workers, whose fundamental studies were based on the employment of the latest tool of biological research, the labeled or isotopic molecule, which is one of the useful contributions of nuclear physics, whose more spectacular application resulted in the atomic bomb.

It is important to realize that proteins are quite diverse in their function, varying from the circulating plasma proteins, the hemoglobin imprisoned in the red cells, the protoplasm of tissue cells, to the hormones and enzymes, all protein molecules. Secondly, proteins vary in size and shape, from the relatively small insulin molecule to the tremendous globulin, which has a molecular weight of 250,000. Shape varies from the relatively spherical contour of albumin to the long, stringy appearance of the fibrous proteins such as gelatin and keratin. Thirdly, proteins vary in their amino acid composition, which is probably the reason why one protein must be broken down to amino acids before another protein can be synthesized.

Amino acids circulate in the blood like glucose probably because of the fact that they act as a medium of exchange between the proteins of the food and the various proteins within the body. The actual amount of amino acids circulating in the plasma is similar to the amount in glucose, i.e., about 80 mg. per 100 c.c. Changes in their level have received rather limited study. If there is any analogy with the information contributed by the study of the glucose level in the blood, a great field for future research should follow further investigation of the concentration of amino acids in the blood.

Historical Survey

In L. B. Mendel's book on nutrition, *The Chemistry of Life,* there is an interesting discussion of the history of the various food elements. It is only within the past hundred years that the Hippocratic idea of a universal food element was shown to be untrue. Prout in 1830 first showed that there were at least three different food elements, i.e., carbohydrate, protein and fat. Mul-

der, a Dutch biochemist, first gave protein its name, although Magendie first noted that protein is characterized by its content of nitrogen, not possessed by carbohydrate or fat. This contribution of Magendie, however, was overshadowed historically by the studies of Lavoisier, who preceded him and Liebig, who followed him.

The early workers in nutrition felt that protein was a very important and essential element in the diet, an idea which remained unchallenged until the work of Chittenden, who not only showed that a low protein intake in normal individuals was consistent with health, but who also claimed that any increase in the protein intake was detrimental to general health. This idea was supported by the traditional view that a high protein intake is harmful in diseases of the kidneys. Because of this and other reasons, most physicians in the early part of this century tended to neglect protein as an essential part of the diet, particularly in disease.

It was only after World War I that the importance of protein was re-emphasized. This change was based upon observations of Maver and of Kohman, of Mendel and Peters, and later of Weech and others, who showed that nutritional edema was directly connected with a fall in the plasma proteins (hypoproteinemia). In 1933 Jones and Eaton first showed that postoperative edema was due to protein depletion. In the past ten years numerous observers have shown beyond question the importance of protein depletion in the production of postoperative difficulties of many kinds. We may accept as proven the importance and even the essential nature of protein intake in the maintenance of normal function, particularly during and after operation.

This does not mean that the other elements in the diet, i.e. water, energy, vitamins and salts, are not also important. Indeed, it is only by a consideration of all of them that normal physiological function may be maintained. However, the importance of calories and vitamins in particular has been so emphasized in recent years that protein needs have slipped into the background, and it will be part of my purpose to bring forward into more realistic juxtaposition its relation with the other elements. An adequate intake of this element is necessary in order to maintain normal function of surgical, and indeed, of all patients.

Relation of Body Protein to Plasma Albumin

Plasma albumin is the most important fraction of the plasma proteins as far as the physiologic function of the circulating plasma is concerned, and is involved in nutritional and other types of deficiency. Yet this protein comprises a relatively small total amount, i.e., about 150 gm. There are by contrast many thousand grams of protein in the rest of the body. The quantitative relationship between albumin and the rest of the body proteins seems to be a relatively constant one during conditions of depletion as well as during repletion. This is an important consideration because it explains the reason why such tremendous amounts of protein are necessary to correct an albumin deficiency in the blood, i.e., so much is required to replace body protein at the same time as the plasma albumin is being corrected. From the data of Weech as well as from data obtained in our laboratory, this relationship is expressed by a ratio of thirty to one. In other words, in a nutritionally protein-deficient individual, only 1 gm. out of every 30 gm. ingested and assimilated is available for the correction of hypoproteinemia. The rest is required for the correction of deficiencies in the rest of the body.

The Recognition of Protein Deficiencies

Exact laboratory methods for the recognition of protein deficiencies have been used by many workers in the field. The results may be studied by those interested in the mechanisms. They are usually too complicated for ordinary clinical use. Moreover, these laboratory methods have been used so extensively and have been correlated with such definite clinical manifestations that the average clinician need not worry about carrying them out. These laboratory methods will be merely mentioned but not described. They are (1) determination of nitrogen balance, (2) biopsy of the liver with study of its histological appearance and/or chemical composition, and (3) study of the blood including both the hemoglobin in the red cells as well as the plasma proteins.

Of the three methods mentioned above, studies of the blood have probably been the most extensive, particularly plasma protein determinations. The difficulty with such measurments is the frequency with which normal values are obtained in patients who are obviously protein-deficient. The reasons for this discrepancy are many, but have been discussed in detail elsewhere. Suffice it to say that such determinations are really not necessary and that the average clinician can meet his responsibility in most cases in a satisfactory manner, without recourse to such measurements, by knowledge of the bedside features of protein deficiency, which will now be discussed.

Acute Protein Deficiency. This type of deficiency is easy to detect from the history alone. Any patient who has lost a significant amount of protein-containing fluid will suffer from acute protein deficiency, particularly acute hypoproteinemia. It will perhaps suffice to mention the clinical conditions under which such loss occurs, noting that in many cases hemoglobin as well as plasma protein is lost at the same time. These conditions include the following: severe hemorrhage, extensive burns, intestinal obstruction, peritonitis, empyema, pneumonia, severe tissue injury, extensive draining wounds or sinuses.

In all of these conditions, it is clear that protein-containing fluid leaves the blood stream either to the outside, into the tissues, or into the body cavities. The clinical manifestations produced by such acute loss will vary with its degree and rapidity. The production of surgical shock is the most severe result of such loss, but abdominal distension from edema of the intestinal tract as well as suppression of urine from a fall in the colloidal osmotic pressure of the blood will also be observed in many instances.

Chronic Protein Deficiencies.—Here the loss of protein occurs because of tissue breakdown with excretion of urea and ammonia in the urine, and therefore may be measured by calculating the total nitrogen output in relation to the intake. Some loss of nitrogen is normal, but in certain diseases, particularly in fever and extensive trauma, this destruction is tremendous and may lead to the loss of as much as 2 pounds of muscle protein tissue a day.

The history of the case will obviously enable the physician to know whether excessive loss of protein tissue has actually occurred. But more important, a history of the dietary intake will be decisive in evaluating the degree to which such a loss has been prevented. Obtaining a dietary history is not always easy, but a serious attempt should be made, and inquiry as to the amount of milk, meat and eggs will often indicate how much or how little proein the patient has actually taken.

Bedside manifestations of chronic protein deficiency are numerous and even in absence of a history should lead the physician to a correct estimate. Loss of body weight with due regard to the influence of edema, both hidden and overt, is of obvious importance. Faulty wound healing is a late manifestation, as is the appearance of decubitus ulcers. An impaired resistance to infection and a reduction of hepatic function have also been shown to follow chronic protein deficiency. Nutritional edema is perhaps the most striking bedside evidence of hypoproteinemia; yet it varies tremendously in its appearance and disappearance, and can very seldom be correlated accurately with the level of serum protein. There are undoubtedly many factors beside protein deficiency which determine when and where nutritional edema will appear. Moreover, nutritional edema is not always visible; it occurs in the intestinal wall, thereby leading to various disturbances in gastrointestinal function, and may appear at areas of intestinal trauma as, for example, after anastomoses, and lead to symptoms of obstruction.

The early manifestations of protein deprivation are difficult to describe because they are so nonspecific. There is some evidence, however, to show that general malaise and loss of strength, particularly after operation, and usually attributed to the procedure in many instances, are due to protein deprivation inasmuch as they are often absent when protein starvation is avoided.

Therapy

It is an oversimplification to say that ordering an adequate high-protein diet will prevent or cure protein deficiencies. In the first place, special devices are frequently necessary in sick patients in order to assure an adequate intake. In the second place, the parenteral channel is sometimes needed for one or more reasons. In the following discussion treatment will be divided into the correction of acute in contrast to chronic deficiencies.

Acute Protein Deficiencies.—Therapy is usually rather simple and effective, because a transfusion of either whole blood or plasma replaces at once what is missing, and is permanently effective as long as no further losses occur. It is obviously important that these acute losses be replaced as soon as possible, and indeed in the case of bleeding at operation, the loss can be corrected almost at once. On the other hand, when the loss occurs through damaged capillaries, there is some evidence to show that correction is best made several days later, when the damaged capillaries are no longer permeable, in order to insure against further loss of the injected material. Such delay, however, is obviously dangerous when the loss has been so great as to lead to surgical shock. In such cases, the replacement must not only be immediate, but it must be rapid in order to prevent the irreversible changes which occur when the circulation remains impaired for a long period of time.

Chronic Protein Deficiencies.—There are two general features which should be emphasized. First, an adequate intake must be started at the very beginning—in other words, the first day the patient comes under our care. If protein deprivation persists, the problem becomes magnified greatly. It is much harder to correct a chronic protein deficiency than it is to prevent it. Second, an adequate protein intake cannot be left to chance nor to the usual types of dietary procedures.

The oral route is obviously the best for the administration of protein. It is not only the cheapest, but it is probably the most effective physiologically. Protein may be administered orally either in the form of whole protein separated from natural food, or as a part of natural food substances. Protein may also be administered in the form of amino acid mixtures which in some instances have advantages over whole protein—for example, when it is advisable to spare the need for digestion, which may be impaired. When the physician wishes to administer larger amounts of protein than can be assimilated in the form of whole protein, amino acids may be used, or when he wishes to combat hyperacidity, amino acids are better buffers than whole protein. It should be emphasized, however, that hydrolyzed protein must have a high biological value, and that a large enough amount must be given each day. Thus far, the taste of hydrolyzed protein preparations has been a distinct disadvantage except in the case of tube feeding.

The problem of anorexia in sick patients requires devices which permit the ingestion of a large amount of protein in a relatively small volume, preferably as liquids rather than solids. It is probably permissible to sacrifice some of the caloric requirements in order to insure a large protein intake. As a working rule, 100 gm. each of protein and glucose may be set as the probable minimum intake. By adding skimmed milk powder and pure casein to whole milk properly flavored, one may devise a palatable liquid drink which in one glass will contain about 25 to 35 gm. of protein and about 300 to 400 calories. This may then be ordered three or four times a day, and the physician thereby is assured that protein starvation will certainly not occur.

Larger amounts may be given to extremely malnourished patients. As much as 200 to 300 gm. of protein and up to 5,000 calories have actually been given to hospital patients when adequate supervision and care were provided. Tube feeding may sometimes be necessary and, of course, presents no unusual problem except for the necessity of using liquid food.

Parenteral Protein Feeding.—The parenteral route for the injection of needed protein must only be used on the most definite indications. This is so because any parenteral, particularly intravenous injection, is potentially dangerous. While the incidence of untoward reactions may not be great, they do occur and will obviously be less when this method of therapy is used least. On the other hand, the injection of protein material intravenously will permit great improvement in surgical and other care, and even be directly responsible for the saving of human life, particularly in the case of transfusions.

Protein can be injected intravenously either in the form of plasma and whole blood or as solutions of amino acid mixtures which are at present available only as preparations of hydrolyzed protein. The two forms of parenteral protein administration usually have entirely different indications but are frequently necessary in the same patient, but usually at different times.

Whole protein, in the form of whole blood or plasma transfusions, generally is indicated for the correction of acute protein deficiencies, as discussed above. Sufficiently large amounts must be given, usually a liter or more, and adequate precautions taken. In the case of chronic protein deficiency, whole blood and plasma may also be indicated, but usually are an adjunct to the use of amino acid mixtures and not the sole method of introducing protein as food.

For parenteral protein feeding, plasma is much more expensive than amino acid mixtures and has a further disadvantage of introducing protein in an unphysiological manner. It is probable that the protein thus introduced is broken down to amino acids before being utilized. By contrast, appropriate amino acid mixtures represent the physiological manner in which food protein is assimilated from the gastrointestinal tract. The use of amino acids makes it possible now to furnish an almost complete parenteral diet. Up until the introduction of hydrolyzed protein for parenteral use, such patients suffered protein starvation. Now, one may give one liter of intravenous fluid containing four of the five essential nutritional elements, i.e., water, glucose, amino acids and salt. This is possible because at least one preparation, i.e., Amigen solution, contains in one liter 50 grams of hydrolyzed protein, 50 grams of glucose and 2.5 grams of sodium chloride plus minimal amounts of other salts. As utilized by the author, 1 liter of this solution is given in the morning and one in the afternoon during periods when the patient is unable to eat. Adequate vitamins are given separately.

The indications for the use of the parenteral channel are many, including primarily those patients unable to take any nourishment by mouth, or patients in whom complete rest of the gastrointestinal tract is indicated. This includes patients with intestinal obstruction, vomiting from any cause, general peritonitis, postoperative anastomoses, certain cases of ulcerative colitis or regional ileitis, and advanced malnutrition. In addition, the parenteral route will also be utilized as a supplementary method of introducing protein nourishment in patients unable to take a large amount of protein by mouth.

The danger of reaction following intravenous injections has been studied rather widely. It is very real in the case of both whole blood and plasma transfusions, and is also present in such complex mixtures as hydrolyzed protein. In a series of 3,000 consecutive injections of Amigen solution by the author, twenty-two reactions, or an incidence of 0.8 per cent occurred, considerably less than was seen with plasma and whole blood transfusions during a similar interval. Contraindications to the injection of hydrolyzed protein are, first, any solution which is not absolutely crystal clear, and second, the development of any sign of sensitivity. Pyrogenic reactions, on the other hand, while they call for discontinuance of the injection, are not contraindications in a strict sense, since subsequent injections may be carried out without necessarily provoking a similar effect.

REPORT OF ATOMIC BOMB CASUALTY COMMISSION

A number of interesting facts relating to the Japanese who survived at Hiroshima and Nagasaki were disclosed in the report of the Atomic Bomb Casualty Commission released by the War Department at a recent press conference held in the office of the Surgeon General.

Following are some highlights of the commission's report, which was reviewed and cleared by the Atomic Energy Commission prior to issuance:

"Members of the commission have been impressed during their observations of atomic bomb survivors by the fact that many of the burns have healed with accumulations of large amounts of elevated scar tissue, the so-called keloids," said the report.

During the months of October and November, 1945, a study was conducted on 124 male inhabitants of Hiroshima. Examinations disclosed that, in 43 cases, the number of spermatocytes in the ejaculated sperm was less than 5,000 per cubic millimeter, or "absolutely sterile," in the words of Prof. Tsuzuki. Ten other cases were "relatively sterile" and the remaining 71 were normal.

"A reformation of the spermatocytes occurs in one month, so the recovery of damage to spermatocyte formation will be delayed more than that of the damage of white blood cells. The shorter the distance, the more severe was the damage. The damaging influence on the number of spermatocytes was observed in the area within a radius of three kilometers (about two miles) from the ground center. Within a radius of 2.5 kilometers there appeared some sterile cases. Within a radius of 1.5 kilometers one-half of the cases showed sterility."

Women who were in an early stage of pregnancy "have taken a normal course since the bombing," said Dr. Tsuzuki.

"It is already experimentally proved both in botany and zoology that there is a possibility of producing malformation of descendants when the sexual cells are affected in some degree by radioactive energy. The question, if this fact is applicable to the human beings or not, will be made clear by further observations.

"We have already clear evidence that the human sexual cells are also affected by the atomic bomb injuries. There is a possibility of malformation of the descendants, if the sexual cells should be affected selectively, without any severe damage to the other organs or tissues.

Heretofore, conflicting figures have been presented on the number and character of casualties at Hiroshima and Nagasaki. Dr. Tsuzuki quotes the Hiroshima prefecture as estimating, 19 days after the explosion, the dead at 46,185; the missing at 17,429; the severely injured at 19,691; slightly injured, 44,979, and other sufferers at 235,656. Six months after the catastrophe, the toll of dead and missing stood at 92,133, excluding the military dead. The total number of Hiroshima dead may be set at 100,000, according to the Japanese professor. The Nagasaki prefecture set that city's toll at 23,753 dead, 1,924 missing, 23,345 wounded and 89,025 other sufferers.—From *News Notes,* Office of the Surgeon General, April, 1947.

THE RELATIONSHIP OF INFECTIOUS AND SERUM JAUNDICE

JOHN G. RUKAVINA, M.D., and EDWARD L. TUOHY, M.D.
Duluth, Minnesota

EPIDEMICS of jaundice are a regular war accompaniment, and the more widespread the conflict, the more civilians and military personnel fall victims. This fact has made it certain (without the added incubus of the recent war) that this form of infectious jaundice is a transmissible disease and, as such, must be distinguished from jaundice caused by drugs, toxins, degenerative and infectious processes of known bacterial origin, and neoplastic and calcific obstruction. The older term "catarrhal jaundice" is gradually yielding place to the term "infectious hepatitis." The older term greatly overstressed the factor of extrahepatic ductal swelling. Using the material from a local epidemic of infectious jaundice occurring in 1944, Fee and Tuohy[44] reported a high incidence of this type, and by profile studies of various laboratory procedures (with special emphasis upon information provided by quantitative urobilinogen estimations in the stool and urine) they established means of differentiating intra- and extra-hepatic jaundice.

The accepted entity of infectious jaundice provides a needful opportunity for clinicians to familiarize themselves with the habits and propensities of viruses in general: their immunological identification, selective localizations and the mechanisms of natural defense of the host. Since biological inhibiters and mold extracts are known to lack specificity in most bowel infections, the maintenance, for example, of the gamma globulin fraction of the circulating and tissue plasma, with a background of a good functioning liver, becomes paramount. Furthermore, behind this liver adequacy stands a sufficient diet with suitable protein content. Now that a general consensus obtains as to the transmissibility of the jaundice virus (of various types), many papers and reports are in the current literature dealing with the routes of entrance into the host, and how defense against the virus may be planned. Identification of the virus comes first to mind: whether one common virus accounts for this transmissible type of jaundice, or whether there are several distinct or possibly related forms. Since the morphological tagging of viruses is still far behind that of living bacteria, measures other than morphological identification are utilized.

Another form of intrahepatic jaundice, also closely identified with the events of the war and known as "homologous serum jaundice," is presently furnishing many fruitful studies. It first got prominent attention after some of the earlier military recruits were vaccinated for yellow fever. Later on as transfusions of banked blood and the giving of plasma became routine procedures on the battle field, this type of jaundice in some areas exceeded the totals of infectious jaundice where no transmission via the route of human blood could be incriminated. Lest it be assumed that this only concerns the armed forces in action or in the various hospital cantonments, the writers wish to report two cases of homologous serum jaundice, one terminating in death, with the same subacute liver atrophy so well described by the various authors reporting their military experience. In each instance these women developed their jaundice sixty to eighty days after abdominal operations, in the course of which blood transfusions were given as precautionary measures.

Doubtless, since the termination of war, there has been less and less epidemic jaundice. The usual caution of directors of blood banks will, of course, dictate the rejection of all donors with recent illnesses, not to mention previously jaundiced persons.

One of the authors (J. R.) has reviewed the extensive literature bearing upon the relationship between infectious hepatitis and serum jaundice. This digest is offered in an attempt to find out how much these entities have in common and wherein they differ. It is hoped that the reader will find stimulation and understanding in reviewing what our active medical men have been able to accomplish in this field of research despite the overwhelming difficulties and confusion of a military service spread around the world. World War II has provided much material for

---

From the Department of Medicine, The Duluth Clinic and St. Mary's Hospital, Duluth, Minnesota.

these various studies. Since routine epidemic and endemic infectious jaundice has long been studied, the liver damage associated with serum jaundice has been conspicuously stressed.

The following primary aims are set forth in attempting to group the recent studies: (1) to establish with certainty the entity of homologous serum hepatitis; (2) to catalogue the consensus of opinion as to its experimental reproduction; (3) to point out the likenesses and dissimilarities of homologous serum hepatitis and infectious hepatitis, and (4) to demonstrate in the last analysis that the "artificial" disease has a higher mortality rate, longer incubation period, and a reduced element of contagion.

Transmission of Infectious Hepatitis Via Natural and Experimental Routes

Since infectious hepatitis occurs in well-known epidemics, many studies attest the correctness of this clinical inference.[3,9,11] The agent is present in the blood stream before the onset and during the jaundice; it is also present in the feces and possibly in the nasal washings in the acute stages.[19] MacCullum and Bradley,[24] Havens et al[20] used such material establishing effective proof of transmissibility. The latter group fed nine volunteers samples of infectious sera or feces, producing the disease in five after an incubation period of from twenty to eighty-four days (average thirty-seven days). Neefe and co-workers[32] fed pooled specimens of feces from patients with infectious hepatitis to twelve volunteers, hepatitis occurring within twenty-six days in six of the twelve subjects. They were able to prove conclusively, using infectious materials from an epidemic at a boys' and girls' summer camp near Philadelphia, that the agent responsible for the epidemic was water-borne. This experiment appeared to them to be the first satisfactory evidence of the natural water-borne transmission of a virus disease to man.

The traditional use of laboratory animals as vectors or intermediary hosts has met with failure because animals are refractory. Cameron,[5] Paul et al,[37] Findlay and Martin,[13] Oliphant and coworkers,[36] Sawyer and his group,[40] and others made such attempts without infecting the animals used. The work of continental European investigators indicating positive results lacks confirmation in this country.[37] Recently MacCallum and Miles[25] rechecked the question of animal transmission. Inoculating Wistar rats, that had been placed on a diet deficient in protein, with blood and feces of infections hepatitis patients, followed by nine blind passages of tissues of these rats, these men were able to produce liver necrosis, and/or hemorrhage into the lymph nodes, gastric and intestinal walls and tissues of the lung. Thus these studies suggested to them that they were dealing with a transmissible disease caused by a virus, and hinted that hypoproteinemia in their animals made their livers susceptible. Bearing this new evidence in mind, one finds clinical support in the recent report of Snell, Wood, and Meienberg.[41] They studied thirty-two cases of serum jaundice occurring on an average of eighty-four days following military trauma. All had received blood or plasma after injury. The mortality rate was relatively high—19 per cent. The seriousness of the course of the disease in wounded men was attributed by them to a nutritional depletion which added to their vulnerability.

Serial passage of the disease in man has been reported on two occasions.[18,19] By using the human volunteer technique some of the properties of the agent have been determined.

1. Both the icterogenic agent in homologous serum jaundice[36] and that of infectious hepatitis[18,19] have been found to be heat resistant at 56° C. for one-half hour and also to pass bacteria-tight filters.
2. As in serum jaundice, the agent is present in the blood stream during the active phase.[5,19,24]
3. Its presence in the feces[14,19,24] and urine[14,46] has been similarly demonstrated.

Numerous substances have been used in the production of infectious hepatitis by the oral route. Voegt[46] claimed to have caused the disease successfully by oral administration of duodenal fluid, urine, and hemolyzed red blood cells. MacCallum and Bradley,[24] by feeding infectious feces to volunteers suffering from arthritis, claim to have produced the disease, although their results with nasopharyngeal washings were less convincing. Havens and co-workers[19,20] added weight to these observations by their studies of material secured from American and British troops in the Middle East and Mediterranean area. They gave fecal material in capsules, as well as urine and stool extracts, which had been filtered and dried. Two of three volunteers contracted jaundice after twenty to twenty-two days.

A number of reports emphasize the parenteral route as a means of producing the disease. Cameron,[5] using serum and whole blood secured from infectious cases, produced the typical picture in six of seven volunteers by intramuscular injection. Voegt[46] (9), in an earlier monograph, and others[19,24,36] using various parenteral routes reported similar results.

Homologous Serum Hepatitis

Homologous serum jaundice, a highly artificial entity, presents a more difficult problem in etiology. By definition, it is a form of hepatitis which usually occurs from six weeks to six months after the injection of certain samples of whole blood, serum, or plasma.[22] It implies that blood drawn from a nonjaundiced individual, or from one not known to be ill at the time, has gone into a blood bank pool. There is no doubt in the minds of many students of liver pathology that this entity has been commonly overlooked in the differential diagnosis of hepatitis; and with the greater use of blood and blood products (especially in view of the early release of excess armed forces plasma) this question becomes even more important. Peculiarly enough, serum jaundice has not been observed as yet after the injection of normal serum albumin and normal serum gamma globulin which were derived from 250 to 5,000 bleedings pooled for plasma fractionation.

The literature is replete with reports that the disease has been associated with the use of prophylactic measles serum.[26,28,29,38] MacNalty[26] observed jaundice among thirty-seven of eighty-two to 109 persons who had received this substance from the same material pool. Propert[38] reported not only that seven children developed jaundice after injection of convalescent measles serum but that there was definite evidence that two playmates developed jaundice approximately two months after contact with the injectees! Mumps serum has also been implicated.[2,27,28,31] One study[27] noted that hepatitis developed in 101 of 266 men inoculated with mumps convalescent plasma. Yellow fever vaccines in human serum drew especially widespread comment and attention due to the experiences of the United States Army[6,7,8] in 1942. Findlay, Martin, and Mitchell,[16] in an intensive study of 689 cases of yellow fever vaccine hepatitis, occurring in military personnel during World War II, stressed the importance of the clinical, pathological, etiological, and epidemiological features. Great emphasis was also placed on four cases suffering from post-inoculation hepatitis without jaundice, suggesting to them the greater need for consideration of hepatitis occurring in a forme frustre without recognizable jaundice. More emphasis, then, must be placed on serum hepatitis *sine ictero* in living subjects. Turner[45] and his colleagues carefully studied 4,083 cases of post-inoculation hepatitis at Camp Polk, Louisiana, the hepatotoxic agent being present in yellow fever vaccine, lot 369. The clinical picture with especial reference to the nervous system manifestations in severe cases was stressed. Other studies[12,15,17,36,42] have added further data to our increasing knowledge of post-inoculation hepatitis.

Reports dealing with the experimental injection of some of these sera are of interest. Oliphant[36] experimentally produced jaundice in volunteers by inoculation of two lots of yellow fever vaccine containing pooled serum, and also by inoculation of serum from eleven patients who had previously received yellow fever vaccines carried in human serum. Evidence was also presented that the icterogenic substance was absent from the blood stream two and one-half months after the disappearance of the jaundice. They made the novel observation that this agent might be neutralized with ultra-violet radiation.

Beeson[1] reported that seven persons who had received transfusions of blood or plasma at the time of an injury or surgical operation developed jaundice one to four months after the transfusion. Steiner's experiences add to these reports.[43] Rappaport[39] observed thirty-two cases of jaundice in military personnel following transfusion with plasma or blood. He opined that, apart from infectious hepatitis, transfusions may serve as the commonest current cause of jaundice in the armed forces. Jaundice due to plasma or serum has been further noted in scattered reports.[4,28,29,34] Neefe and others[34] related the 100 per cent occurrence of hepatitis in nine men inoculated experimentally with plasma or yellow fever vaccine containing human serum. Bradley, Loutit, and Maunsell[4] discovered that 57 per cent of their cases developed jaundice forty-nine to 107 days after infusion with pooled serum. Morgan and Williamson[29] commented on the fact that 18 per cent of their patients developed jaundice forty-nine to 107 days after transfusion of liquid pooled plasma or reconstituted dried serum.

The agent of serum hepatitis produces jaundice inconsistently when administered by the parenteral route. Oliphant and co-workers, using yellow fever vaccine and serum for vaccine-induced jaundiced persons, caused the disease to appear in thirty of 189 cases tried. MacCallum and Bauer observed two cases of jaundice when five volunteers were studied. Neefe[34] reported varying results with the inoculation of mumps convalescent serum, mumps passage material, and yellow fever vaccine. Paul[37] and others, reported a higher incidence of positive takes.

Serum jaundice has been transmitted in one case[23] by feeding serum and in three cases in which the icterogenic serum was swallowed accidentally by laboratory workers.[41] On the whole there is basic agreement by most observers that the oral administration of feces from homologous cases of serum hepatitis does not produce hepatitis. There is some evidence that nasopharyngeal washings carried the etiologic virus.[13] One is hard pressed to explain the observations of two authors[34,38] who felt that through contact with patients suffering from serum hepatitis, four persons developed a jaundice that did not appear to them to be the epidemic type. Were these true contact cases?

Differences of the Disease Entities

Thus, the problem of similarity or dissimilarity of the agents of serum and infectious hepatitis, despite all this research, still retains some secrets. The similarities have been commented upon; the differences remain of prime interest. Many investigators have emphasized that the death rate is higher in serum hepatitis than the 0.2 to 0.4 per cent characteristic of infectious hepatitis. Neefe et al[33] point out the fact that the temperature in infectious hepatitis usually is observed to be above 100°F. (orally), while that of serum jaundice usually does not exceed 100°F. Further they emphasize the fact that the incubation period in the artificial disease is prolonged sixty or more days. However, one must continually make allowance for the variable icterogenic "capacity" of the sera used which may well explain the variation in rates at which serum jaundice is produced as well as the difference in length of incubation period. Transmission differences require consideration. Multiple routes in experimental transmissions are common in infectious hepatitis, while efforts at feces transmission of serum hepatitis have generally met with failure[32]—hence the observation that it is not a relatively contagious disease.

The Problem of Homologous Cross Immunity

Since a number of investigators do not believe that the aforementioned criteria are sufficiently adequate for differentiation, antigenic studies involving immunity and cross immunity techniques have been utilized.

There is general consensus that a single attack of infectious hepatitis produces a degree of immunity.[5,16] Further, the infrequency with which this lesion occurs after thirty-five years of age suggests an age-acquired immunity, or an apparent subclinical childhood attack. Neefe and his group[33] have demonstrated experimentally that immunity to serum jaundice following infectious hepatitis does exist, while volunteers were found to be resistant to reinfection with the infectious hepatitis type up to at least eight months after recovery from hepatitis which had been induced by the same agent.

Homologous immunity in serum hepatitis has been discussed by Oliphant[35] who reinjected ten persons with yellow fever vaccine twelve to eighteen months after hepatitis had been induced by inoculating yellow fever vaccines or samples of similarly induced icterogenic serum. Ten normals were used as controls. Three of the latter developed hepatitis while none of the test group were so afflicted. Neefe[33] confirmed this view.

The data on cross immunity, however, leaves much to be desired. The assembled data presents conflicting conclusions. One investigational group[27] reported that of an army unit of 175 men developing serum hepatitis following prophylactic inoculation of a mumps convalescent serum, eleven of these cases had a history of "catarrhal" jaundice in childhood. Another group[16] was impressed by the apparent reduced susceptibility to serum hepatitis of persons who had previously had the infectious type. In striking contrast, Witts,[47] quoting Gordon, stated that previous homologous serum hepatitis might actually increase susceptibility to infectious hepatitis. Oliphant's[35] view that "recovery from homologous serum jaundice results in immunity to reinoculation with serum from acute cases of infectious hepatitis or with icterogenic yellow fever vaccine and that the immunity persists for at least twelve to eighteen months" has been challenged. Lack of data as to the age of the subjects seems to nullify the above observation on the basis of decreased susceptibility to infectious hepatitis of persons over thirty-five years of age.

These recent investigations concerning cross immunity might be considered as pioneer work. Currently, Neefe and co-workers,[33] further exploring the problem, conclude that the hepatitis which occurred in the serum hepatitis resistant test group (five cases), following inoculation with infectious hepatitis test material, was not due to "reactivation of the serum hepatitis agent, to reinfection with that agent after disappearance of the previously demonstrated resistance or to breakdown of that resistance by an overwhelming dose of the same agent." Rather they felt that the hepatitis was due to the infectious material with which the cases were reinoculated. The absence of cross immunity suggested to them a difference either on the basis of an antigenic variation in strain of a single type of virus agent or on the basis of two different types of virus agents. These researches bring up the possibilities of various strains of virus as is well known with the higher bacteria.

Summary

1. Despite the difficulty objectifying virus types, these known forms of hepatitis are accepted as viral in origin and are just as definite etiologically as is measles or small pox.

2. Homologous serum hepatitis brings in a route of human transmission that involves the provinces of vaccine prophylaxis and human blood or serum replacement.

3. Paul and Havens[37] and Neefe and Stokes[32] have commented upon the relationship existing between the causal virus of serum jaundice and infectious jaundice and think they are distinct. It will be recalled that all viruses may have common propensities.

4. There is no need of denying anyone needed blood, plasma or serum; but the relatively small chance of transmitting serum jaundice should tighten up the indications for transfusions and the careful survey of donors for blood banks.

A PLAN FOR THE DETECTION OF THE SOURCE OF RECTAL BLEEDING

HAROLD E. HULLSIEK, M.D.
Saint Paul, Minnesota

BLEEDING from the rectum, either as the patient's chief complaint or as one of several symptoms, is of common occurrence. It is frequently disregarded, judged as meriting little concern, but it should always be investigated since it may be the first evidence of malignant disease. The source is to be found and, if possible, eradicated. If this is impossible, one should at least be able finally to assure one's self and the patient of the absence of serious disease. One of the reasons for the frequent neglect or mistreatment of individuals with this complaint is the lack of a plan in the search for its cause.

A PLAN FOR THE DETECTION OF THE SOURCE OF RECTAL BLEEDING

I. History
II. Inspection.
III. Digital examination.
IV. Anoscopic examination.
    A. Cause found and easily remedied.
    B. Cause found requiring lengthy or extensive treatment
    C. Cause not found.
V. Proctoscopic examination.
    A. Cause easily remedied.
    B. Lengthy or extensive treatment.
    C. Cause unfound.
VI. X-ray of colon.

In a recent and very complete article on the subject, an author states that "a complete proctologic study including proctosigmoidoscopic examination, examination of the stools, and an x-ray of the colon" should be done for all patients with rectal bleeding. Now the plain fact is that this is not necessary for all patients of this type, and, while every practitioner knows this, often he is not certain as to the one in whom it is necessary. The same writer lists some seventy conditions which produce blood in the stool, leaving the reader's mind filled with a bewildering confusion of causes but with few concrete suggestions as to how to proceed. If his rule is followed—and much the same advice is given in most articles on this subject—many patients will be subjected to arduous and unnecessary investigation and expense. On the other hand, if it is not followed, some very serious conditions may remain undiscovered. With the above in mind, I have attempted to arrange a graphic representation of the methods I have for years more or less automatically followed. Before proceeding further, I might say that this discussion does not apply to those persons with massive rectal hemorrhage and in whom the primary concern is the treatment of shock and blood loss.

In all cases involving rectal bleeding, a careful history is of value and is occasionally diagnostic of itself. Is the blood bright or dark, liquid or coagulated? Is it passed unaccompanied by, or mixed with, the stool? Is it merely on the toilet tissue? Estimates by the patient of the amount of blood passed are to be evaluated with caution, but often one may get some idea of the quantity. Do the bowels move daily and as usual for that particular patient, or has there been a definite change in bowel habits? If constipated, what measures have been undertaken to overcome it, and are they successful? If the bowels move frequently, is the movement an actual stool or does it simply represent an urge to move the bowels, producing blood, gas, and a semi-liquid material? Does the bleeding have associated with it itching, burning, or prolapse? If there is pain, what type is it and how long does it last? For example, a sharp cutting pain experienced at the moment of passing the stool and continuing for several hours afterward, gradually becoming less severe, together with streaking of blood, is almost pathognomonic of fissure. How long has the bleeding been going on and does it occur daily? A history of a change in bowel habits of from one or two movements a day to several bloody and watery discharges, to-

gether with weight loss, is of course suggestive of malignancy in a person of middle age. On the other hand, the same story in a young individual is more likely to be an ulcerative colitis. The patient with a story of something protruding after stool, which he is able to replace himself, in all likelihood has no more than prolapsing piles. The search for anything is made much easier by a knowledge of what to look for and where to look, and careful questioning will frequently bring out clues as to both.

Inspection

This should be done with the patient in the left lateral or Sim's position, with a good light, cotton swabs, applicators both loosely and tightly wrapped, probes, a waste basket for the convenient disposal of used material, and a stool for the examiner to sit on at a convenient level in relation to the patient. Most of the things needed for a competent rectal examination are part of every physician's equipment, but unless arranged for a rectal examination, oftener than not, they are not conveniently accessible. I may appear to be stressing a minor point, but I firmly believe that the difference between a very good rectal examination and a very bad one may depend on no more than this. There are a number of conditions causing bleeding which may be seen on inspection. Anal condylomata, an excoriated pruritic skin, minor injuries, or a true anal fissure or ulcer may be the source of blood seen on the toilet paper. A ruptured abscess or the external opening of a fistula, prolapse, prolapsing hemorrhoids, a prolapsing polyp, or an epithelioma of the anus may be easily seen. The common anal fissure in the anterior or posterior commissures may be diagnosed by inspection only, and if a bleeding fissure can be seen by simply everting the anal opening and looking, there is no point in making proctoscopic examinations or taking x-rays. In fact, there is little reason in looking for anything the hard way if it can be found by the easy way first.

Digital Examination

Regardless of the patient's story or the findings on inspection, all these people should have digital examinations. That this point needs to be impressed is remarkable, but experience proves that it does. Too many individuals are given advice and treatment without benefit of examination. The patient should be in the Sim's position with the examiner first seated on the stool, and then standing. The flexor surface of the finger should be directed forward, and then with the examiner standing, it should be directed toward the sacrum, at which time the finger can be made to pass into the rectosigmoid junction in most patients. It is quite impossible to do this with the finger directed forward as in an examination of the prostate. The size of the canal can be calculated and the amount of spasm estimated; if the pain is too great or the canal too small, the little finger may be used and, especially after some practice, much information may be obtained this way. Sphincter tone, abnormal relaxation, and the degree of anal fibrosis may be determined, as well as an estimate of the length of the anal canal. Masses encountered may be tumors, anal papillae, cysts, foreign bodies, including fecal impactions, and occasionally a submucous abscess may be felt. Uncomplicated internal piles cannot be felt. Following the digital examination, an anoscopic examination is to be done for all patients with blood in the stools.

Anoscopic Examination

This gives us first an appraisal of the color and texture of the anal mucosa and reveals at once the presence or absence of inflammation. A hemorrhagic proctitis or a low ulcerative colitis may be seen through an anoscope. The presence of hemorrhoids may be noted, and by rubbing them with an applicator, one finds out whether or not they bleed easily. If no blood has been seen but appears immediately on rubbing the pile, it is very likely that this same pile has bled on movement of the bowels. A pile may have bled rather freely an hour or two before examination and show no sign of bleeding at the time, but if it bleeds on rubbing, it is a likely offender. Is there a discharge and, if so, is it mixed with blood, is it purulent material, or is it mucus? The opening of a draining sinus may be seen, as may a torn crypt. We may see inflamed papillae cryptitis, internal prolapse, tumors, foreign bodies, and now and then parasites. A granulation-filled pocket in the posterior commissure sometimes is productive of blood while giving no other sign.

Having completed the anoscopic examination the question as to further investigation arises. It is either necessary or it isn't. About some patients one is certain, about others there may be some question. It is plain that, for example, a patient with a fissure that bleeds before one's eyes, and whose history suggests nothing else, does not require a proctoscopic examination and an x-ray of the colon. Neither does one with a fecal impaction or a granulating pocket in the posterior commissure. Cancer of the rectum itself has already been ruled out by the digital examination. Further examination may be deferred if the bleeding cause has been found and in addition if it can be corrected easily and quickly and with the loss of little time. Which patients then require a proctoscopic examination?

Proctoscopic Examination

Of all these people, those with obvious and easily corrected conditions may be eliminated at least for the time being, from our consideration. The second group consists of those in whom the source has been found but where the remedying of the condition requires lengthy treatment or extensive surgery. For example, though a patient has obviously bleeding piles, he should have a proctoscopic examination before operation, since even a hemorrhoidectomy is too extensive a procedure to undertake before eliminating the possibility of an accompanying carcinoma. On the other hand, if the bleeding can be stopped by means of three or four injections of quinine and urea hydrochloride into the hemorrhoidal area, little time will be lost, and if additional bleeding occurs from another source, further investigation may be carried out. Do not prolong treatment and do not subject the patient to an extensive operation without having done a proctoscopic examination. The third group in which a proctoscopic examination is to be done is, of course, that in which the source of bleeding has still not been discovered.

Proctoscopic examination should be done before, and not following an x-ray study of the colon. In a large proportion of patients with rectal or colonic disease, the diagnosis may be made by digital, anoscopic, and proctoscopic examination, without recourse to the barium enema and x-ray. On the other hand, not infrequently a patient is dismissed on the basis of negative x-ray findings alone, while having a tumor which, although justifiably missed by x-ray, can be seen by the proctoscope or felt by the finger. Proctoscopic examination should be done following preparation by means of a plain water enema and, if desired, may easily be done in one's office. Unless one confines his work to proctology, he is unlikely to have a proctoscopic table, but the procedure may be carried out satisfactorily on the ordinary examining table with the patient in the knee-shoulder position. Through the proctoscope the color and texture of the mucosa is noted, and the presence or absence of inflammatory change or of ulcers may be visualized. Anomalies in the size and direction of the lumen, varicositis, endometriosis and tumors may be seen. Blood may be seen and, if the examination is made carefully, it sometimes can be clearly seen to be coming from higher up in the sigmoid than the area being viewed. It is clear that there will be a number of patients in whom, up to this point, no bleeding source has been found, who will now, by means of the proctoscope, be eliminated as candidates for further investigation. Certain conditions will become apparent, suggesting definite lines of treatment of longer or shorter duration, or operative procedures of greater or lesser extent. Which patients should be subjected to examination by means of the x-ray?

Again we have each patient falling into one of three classes. The first class consists of those in whom the bleeding point has been found and is easily corrected. A patient with a hemorrhagic proctitis limited to the rectum, for example, need not have a colon film. If treatment can be easily and quickly carried out, x-ray may be deferred for the time being, and if no recurrence of the bleeding is noted, it need not be done at all. A polyp in the rectum is one of the few findings which merely show that my plan is not an inflexible one. Rectal polyps are accompanied by polyps beyond the proctosigmoidoscopic area in 50 per cent of cases; thus, even though a bleeding rectal polyp is found, x-ray of the colon should be done. The second class is made up of those patients in whom the source has been found but who require prolonged treatment or extensive surgery for its correction. The third class is made up of those in whom, as yet, the source of bleeding is still undiscovered.

The above represents an attempt to plan the investigation of patients complaining of rectal bleeding in such a way that, as we pass to the more complicated procedures, a patient is not dismissed at any point without due consideration for his safety. It is an attempt to go always as far in the investigation as we should for security's sake and, yet, not to undertake needless procedures.

THE CRUVEILHIER-BAUMGARTEN SYNDROME

Report of Case

WILLIAM D. SICHER, M.D.
Rochester, Minnesota

PORTAL hypertension, regardless of its cause, results in the development of collateral circulation if it exists long enough and is severe enough. The principal venous communications which may develop to relieve portal hypertension are as follows:[5] (1) The collateral pathways between the gastric veins and the esophageal veins may develop; when these develop excessively, the esophageal varices so frequently encountered in cases of portal hypertension appear. (2) The veins of the colon and duodenum may develop communications with the left renal vein. (3) The accessory portal system of Sappey may play a part in the collateral circulation. Branches pass in the round and falciform ligaments to join the epigastric and internal mammary veins and the azygos vein through the diaphragmatic veins. Occasionally a single large vein may pass from the hilus of the liver to the umbilicus by way of the round ligament. The development of this pathway produces the well-known caput medusae in the periumbilical region. Usually this large single vein is a markedly dilated parumbilical vein; more rarely it is a patent umbilical vein. (4) The intestinal veins may communicate with the inferior vena cava or its branches, by way of the veins of Retzius. (5) Communications between the inferior mesenteric veins and the hemorrhoidal veins may be used. (6) Rarely a collateral pathway between the portal vein and the inferior vena cava by way of a patent ductus venosus may be established.

Another collateral pathway may be established occasionally through the interposition of a small patent upper portion of the umbilical vein, the "Rest-Kanal" of Baumgarten, between the portal system and the epigastric veins as discussed by Armstrong and his associates.[1]

In 1835 Cruveilhier[4] commented on a case previously reported by Pégot[6] in which signs of portal hypertension and dilated abdominal veins with a caput medusae, as well as a parumbilical venous murmur were present. The significant findings at necropsy were (1) a small grossly normal liver, (2) a large indurated spleen and (3) a persistent and dilated umbilical vein. In 1907 Baumgarten[8] reported a case in which the clinical and pathologic findings were similar to those reported by Cruveilhier. In Baumgarten's case microscopic studies of the liver revealed only minimal periportal fibrosis and no true cirrhosis. Baumgarten suggested that patency of the umbilical vein and congenital hypoplasia of the liver and portal system might be the underlying etiologic factors of the clinicopathologic picture described.

To date more than sixty cases of Cruveilhier-Baumgarten disease, Cruveilhier-Baumgarten syndrome and Cruveilhier-Baumgarten cirrhosis have been reported.

In 1942 Armstrong and his co-workers[1] carefully reviewed and analyzed the fifty-three cases which had been reported up to that time and presented two cases of their own. They suggested that the term "Cruveilhier-Baumgarten disease" be reserved exclusively for those cases in which the original criteria of Cruveilhier and Baumgarten were satisfied. These consist of the clinical picture of portal hypertension with excessive umbilical circulation and the necropsy findings of a patent umbilical vein, atrophy of the liver with little or no fibrosis, and usually splenomegaly. These findings may possibly represent a distinct disease entity. They also proposed that the term "Cruveilhier-Baumgarten syndrome" be used to designate a larger group of cases in which the same clinical picture of portal hypertension with excessive umbilical circulation is present, but in which other underlying disease processes are responsible for the clinical picture.

Armstrong and his associates found that only six of the fifty-three cases previously reported and one of their own cases satisfied the original criteria of Cruveilhier and Baumgarten and could be called cases of Cruveilhier-Baumgarten disease. In the rest of the cases the clinical picture of portal hypertension with evidence of excessive umbilical circulation in the form of abdominal murmurs or thrills was present. In some of these cases, however, the portal hypertension was the result of such conditions as cirrhosis of the liver, vascular occlusion or anomaly, or the umbilical vein was not patent and the collateral circulation in the umbilical region was through other chan-

nels. In others the patients were still living at the time their cases were reported, permission for necropsy had not been obtained or the descriptions of the findings at necropsy were inadequate for evaluation.

Since the review just mentioned, at least six more cases[2,3,7,9,10] of the clinical syndrome have been reported, only one of which can be considered as belonging to the group of cases of bona fide Cruveilhier-Baumgarten disease. Thus if this group of cases does represent a distinct etiologic and clinicopathologic disease entity, it is certainly one of rare occurrence since only eight cases have been reported to date to my knowledge.

Report of Case

A white man, a mechanic, twenty-three years old, was first seen at the Mayo Clinic on April 15, 1942. For two years prior to registration he had been employed in an aircraft factory where he had been exposed every few days to various industrial solvents, including carbon tetrachloride, benzene and acetone. In July, 1941, lassitude, mild anorexia and general loss of pep were noted. In February, 1942, he left his job to go to Arizona and to do outdoor work. The symptoms just mentioned cleared rapidly and he felt essentially well for about a month. In March, 1942, nausea, anorexia and diarrhea developed rapidly. Two days after onset he suffered from a fairly severe bout of cramplike abdominal pain, and he began to note abdominal enlargement. Exploratory laporatomy was performed elsewhere. Two gallons (8,000 c.c.) of ascitic fluid were removed and cirrhosis of the liver was found. The ascitic fluid continued to form, and edema of the ankles developed. Paracentesis was performed on two occasions, the last one on April 6, 1942. During the nine days prior to registration at the clinic, ascites was considerably less marked and seemed to be progressively diminishing.

The past history, family history and review of systems were noncontributory.

The patient was well developed and well nourished. He weighed 163 pounds (73.9 kg.). The blood pressure was normal. The liver was enlarged to 2 to 3 cm. below the right costal margin. The spleen was not palpable. There was probably a small amount of free fluid in the abdomen. Peripheral edema and icterus were not noted. Several spider angiomata were present on the hands and arms. The veins of the upper part of the abdomen were enlarged only a little, if at all. A slight thrill could be felt over the lower end of the sternum, and a rough blowing murmur could be heard in this region. This murmur was loudest on inspiration and it was almost abolished by expiration.

Results of urinalysis, determination of concentration of hemoglobin, erythrocyte count, differential blood count, blood smear, routine serologic tests for syphilis, and roentgenograms of the chest were all within normal limits or were negative. The value for serum bilirubin was 3.0 mg. per 100 c.c. and the van den Bergh reaction was indirect. The value for the cholesterol varied between 123 and 175 mg.; that for cholesterol esters was 77 mg., for lecithin 214 mg., for fatty acids 275 mg. and for total lipoids 394 mg. per 100 c.c. of plasma. The prothrombin time was 22 seconds as compared to an average normal of 18 seconds. The sulfobromophthalein test of liver function revealed a grade 2 retention of dye, on the grading basis of 1 to 4. The sedimentation rate of erythrocytes was 1 mm. at the end of one hour by the Westergren method. Urobilinogen was found to be present in the urine in dilutions up to 1:8. None was present in dilutions of 1:16.

The patient was instructed in the use of a high carbohydrate diet and vitamin supplements and was dismissed.

The patient returned to the clinic on July 9, 1942, for a checkup. He was feeling well, he could wear his old clothes, and he thought the fluid had left the abdomen. He had noted edema of the ankles on only one occasion while on a long bus trip. His only complaint was of a mild discomfort in the right upper quadrant of the abdomen immediately after eating. He weighed 179 pounds (81.2 kg.). Physical examination at this time revealed no free fluid in the abdomen. The liver was enlarged and could be felt 2 to 3 cm. below the right costal margin. The spleen was not palpable. There was no telangiectasia. The urine was normal. The value for bilirubin was 1.9 mg. per 100 c.c. of serum and the van den Bergh reaction was direct. The prothrombin time was 21 seconds as compared to an average normal of 19 seconds. A sulfobromophthalein test of liver function revealed a grade 2 retention of the dye. The patient was dismissed with instructions to continue his dietary regimen and the taking of vitamin supplements.

The patient was not seen again until June 6, 1945. He had felt well after his last visit to the clinic until May 13, 1945. He had worked full time and had had no evidence of ascites or edema. He had not been exposed to industrial solvents except for a short period in December, 1944, when he had overhauled an airplane and inhaled fumes from what he called "dope" and "thinner," containing ethyl and methyl alcohol, acetone and benzene. On May 13, 1945, he suddenly vomited some material that looked like coffee grounds and passed a tarry stool. He did not faint and transfusions were not necessary. He was hospitalized in his home community. One week later he noted a rapidly developing, large abdominal swelling. This proved to be due to ascites, and paracentesis was done three times before his return to the clinic. The intravenous use of mercurial diuretics was without benefit. He had no other symptoms except those associated with the volume of his ascites.

On admission the patient weighed 169 pounds (76.7 kg.). He was well developed and well nourished. Blood pressure was normal. Physical examination of the chest revealed slight elevation of the diaphragm on both sides. The abdomen was greatly distended, globular and tense. A fluid wave was elicited. The liver was enlarged to 4 cm. below the right costal margin. The spleen could not be palpated. There was slight edema of the legs, scrotum and penis. Over the lower part of the thorax and upper and lateral parts of the abdomen the superficial veins were dilated (Fig. 1). A thrill was felt in a region measuring about 2 cm. in diameter over the lower end of the sternum and xiphoid process. A loud continuous venous murmur could be heard over this and a surrounding region measuring about 6 by 9 cm. This murmur had a rushing, almost whistling character that could be compared to the sound of wind. It was greatly increased by deep inhalation and was partially subdued by forced exhalation (Fig. 2).

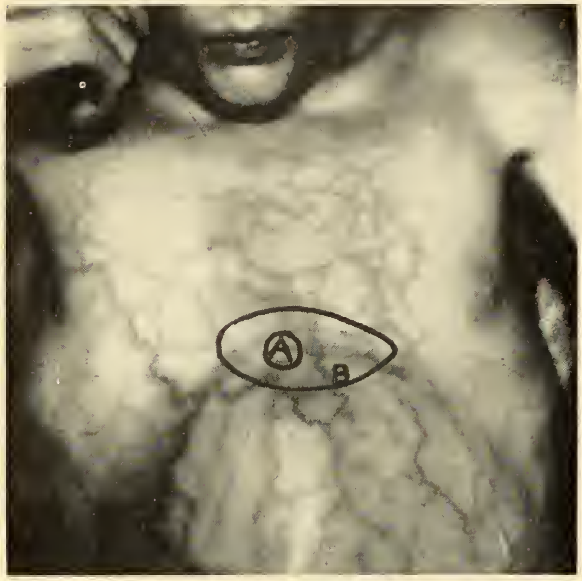

Fig. 1. Dilated venous channels. *A* is region where the thrill was palpable. Large ellipse, *B*, is region over which the murmur was heard (infra-red photograph).

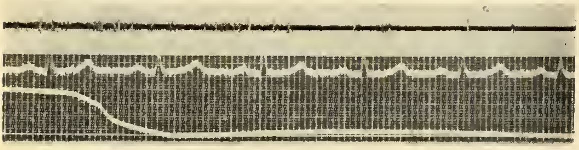

Fig. 2. Stethogram of the abdominal murmur. The top tracing is the sound recording. The middle tracing is the electrocardiogram and the lower one is the respiratory tracing.

The urine was normal. The concentration of hemoglobin was 14.9 gm. per 100 c.c. of blood. Erythrocytes numbered 3,810,000 and the leukocytes 4,700 per cubic millimeter of blood. Roentgenograms of the chest revealed no abnormalities. Roentgenoscopic examination of the esophagus revealed esophageal varices. Proctoscopic examination revealed no varices or hemorrhoids. The value for the blood urea was 36 mg. per 100 c.c. The value for the cholesterol was 123 mg., for the cholesterol esters 62 mg., for lecithin 189 mg. and for fatty acids 156 mg. per 100 c.c. of plasma. The concentration of protein was 5.4 gm. per 100 c.c. of serum and the albumin-globulin ratio was 1.27:1. A sulfobromophthalein test of liver function revealed retention of the dye, grade 3. The prothrombin time was 25 seconds as compared to an average normal of 18 seconds.

For twenty-one days the patient was on a conservative program of 4 mg. of synkamin (vitamin K) by mouth daily, rest and a high-carbohydrate, high-protein, low-fat diet with vitamin supplements. At the end of this period the prothrombin time was 23 seconds and the patient's condition had not changed essentially. Paracentesis was carried out three times in the course of the twenty-one days because of the rapid accumulation of ascitic fluid. The amount of fluid obtained varied between 4,500 and 7,600 c.c. The fluid was clear and straw colored with a specific gravity of 1.011 and it contained 250 cells per cubic millimeter. Abdominal exploration, which was carried out on June 28, 1945, revealed a large hobnail liver and a firm spleen enlarged to about six times the normal size. The spleen and peritoneum were not adherent. Microscopic examination of a specimen removed from the liver revealed portal cirrhosis (Fig. 3). A large, single, dilated vein was found in the falciform ligament. It could not be definitely established whether this was a patent umbilical vein or a paraumbilical vein. Omentopexy was performed.

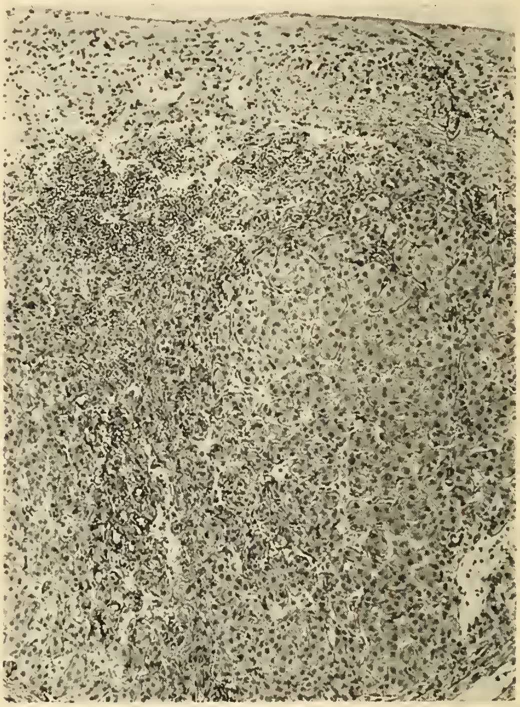

Fig. 3. Cirrhosis of liver (x80).

Comment

Many cases will appear which can be placed accurately in the group with Cruveilhier-Baumgarten syndrome by virtue of definite evidence of disease processes, such as hepatic cirrhois.

SULFADIAZINE GRANULOCYTOPENIA AND THROMBOCYTOPENIA COMPLICATING PREGNANCY WITH SURVIVAL

Report of a Case

ROBERT SUKMAN, M.D., and NELS M. STRANDJORD, M.D.
Saint Paul, Minnesota

THE ROLE of sulfonamides in the production and treatment of agranulocytosis needs further clarification. The neutropenia due to sulfonamides has been classified as an acquired type of allergic as well as specific phenomenon. It is apparent that severe and frequently fatal agranulocytosis may result from the prolonged or intermittent use of sulfonamides. Park[8] is of the opinion that the agranulocytosis due to a sulfonamide drug occurs after an initial sensitizing dose to which there is no reaction. An incubation period of from six to twenty days follows, after which continued use of the drug will result in an allergic reaction characterized by suppression of bone marrow. It is pointed out that large doses over short periods of time (not over one week) will not result in a drug allergy, as will a smaller dosage over a prolonged period of time. When sulfonamides are given for a period of over one week, the patient should be closely checked with daily blood counts, and the drug discontinued if a neutropenia develops. The sensitivity to the drug may be of short duration, and in some cases after recovery from a sulfonamide agranulocytosis the drug may again be used without the production of neutropenia.[1] However, should the sulfonamide be used again, it should be given in ascending doses and with careful hematological control. Patients sensitive to one of the sulfonamides are not necessarily sensitive to another sulfonamide.

The patient with agranulocytosis does not die because of lack of granulocytes *per se,* but due to sepsis developed secondarily in the absence of granulocytes. Cases in the literature[7] have been reported in which sulfonamides have been continued in the face of severe agranulocytosis. If the sepsis was controlled, the bone marrow recovered its ability to produce granulocytes, with a favorable outcome. However, if possible, the toxic agent should be discontinued and another antibiotic substituted to control or prevent sepsis.

At present the drug of choice in the treatment of sulfonamide agranulocytosis is penicillin. Dameshek,[4] and Russek, et al.[9] have reported successful results. This antibiotic substance not only has a bacteriostatic action but also does not depress the bone marrow. In addition to the control of the sepsis it is advisable to use other supportive measures. Whole blood transfusions, if used within twenty-four hours after being drawn, still contain the desired platelets and white blood cells and should be used if available. Folic acid,[3] a liver concentrate in purified crystalline form, has been shown to increase the total leukocytes and also the percentage of granulocytes. If the infection present is caused by an organism not sensitive to penicillin, other antibiotics such as streptomycin may be used. Cameron[2] reports a fatal case in which penicillin controlled the staphylococcus infection but not the pyocyaneous septicemia.

There have been many cases of sulfonamide agranulocytosis, few of which have been reported. Of those reported, the majority of patients with mild attacks have survived; however, in most of the "full blown" cases death has resulted.

Purpura hemorrhagica is a possible serious, though infrequent, complication of sulfonamide drug therapy. Gorham et al.[5] in reviewing eight cases found a mortality of 50 per cent. In three of the four fatal cases the drug was continued after the purpura had occurred. In the four cases in which recovery resulted, the drug was discontinued at the first sign of hemorrhagic manifestations. The total amount of drug administered varied from 5.5 gm. to 48 gm. This indicates a difference in individual susceptibility. Kracke[6] has shown by daily blood counts on patients receiving sulfonamide therapy that there is a depression of the platelets on the first day of treatment and a decided increase in platelets on the first day after treatment is discontinued. Thrombocytopenia precedes the purpura. Therefore, if a marked reduction in the platelets is found, the drug should be discontinued immediately. In practice, platelet counts being rather impractical, one can obtain an accurate estimation of the platelets by examining the differential

smear. With a marked thrombocytopenia the platelets will usually disappear from the smear.

Case History

On August 1, 1946, Mrs. A. K., a forty-three-year-old white woman, entered Ancker Hospital with the chief complaints of hemoptysis, occurring five days previously, and weakness of five months' duration. She was eight months pregnant, the last menstrual period having been on December 3, 1945. She was a para seven, gravida seven. The history indicated that in June, 1946, the patient had developed frequency and burning on urination and she had been given 1 gm. of sulfadiazine three times a day for a period of two days. For the past five months the patient had complained of severe weakness, swelling of the ankles, and fainting spells. For the past month there had been a daily elevation of temperature to 100° orally. To treat an anemia, her private physician had given her iron, calcium and vitamins. One week previous to admission the patient had again been given 1 gm. of sulfadiazine three times a day for a period of six days. Because of the hemoptysis the patient was referred to Ancker Hospital to rule out tuberculosis.

Physical examination on admission revealed a well-developed and apparently well-nourished white woman. The skin and mucous membrane showed marked pallor. The pulse was 128 per minute and the blood pressure was 110 systolic and 82 diastolic. The uterus was enlarged corresponding to an eight months' pregnancy.

Laboratory examination disclosed a hemoglobin of 7 gm., a red blood count of 1,800,000, a white blood count of 2,700, a differential of 51 per cent lymphocytes and 49 per cent polymorphonuclear cells. Few platelets were found on the smears. The x-ray revealed an essentially normal chest.

On the second hospital day, the patient developed a severe diarrhea, having large malodorous, watery, grossly bloody stools. There was marked retching and vomiting. She developed large areas of ecchymosis over the entire body. Her temperature became elevated to 103° and the blood pressure fell to 98 systolic, 60 diastolic. She was given whole blood transfusions and penicillin, 50,000 units every three hours intramuscularly. On the third hospital day, the patient, having become dyspneic and cyanotic, was placed in an oxygen tent. At this time her white count had fallen to 850, and her platelet count was 10,000 (Table I). Many new areas of ecchymosis were found in the mucous membranes as well as in the skin.

Because of the viable fetus and the critical condition of the patient, permission was granted and preparations made for postmortem section if the patient should expire undelivered. On August 4, 1946, at 12:45 A.M., after a total labor of two hours and five minutes, the patient was delivered of a 6-pound 6-ounce living baby girl. The delivery was carried out with the patient in bed, under an oxygen tent and with aseptic technique. A first degree mucosal laceration was sustained, but because of the severe bleeding, sutures were required. Twenty hours post partum, the patient developed severe intra-uterine bleeding, resulting in shock. Intra-uterine packing and oxytocic drugs were used to control the hemorrhage. The pack was removed forty hours later.

On August 6 the patient developed acute urinary retention requiring repeated catheterizations over a period of six days.

On August 8 the patient had an elevation of temperature to 105° orally and developed pneumonia. The x-ray disclosed a patchy infiltration of the mid-portion of the base of the left lung. The purpuric lesions in the skin increased in number and the patient developed jaundice. Penicillin was increased from 50,000 to 100,000 units every three hours. Sixteen days later, x-ray of the chest showed complete resolution of the infiltration.

On August 11 the patient was removed from the oxygen tent. At this time she developed a fecal impaction, following the removal of which she developed an elevation of temperature to 104°.

On August 18 the patient was much improved clinically, so penicillin was discontinued. However, on August 23 the patient developed severe chills and had an elevation of temperature to 103.8°. She had swelling and tenderness in the left breast. A diagnosis of acute mastitis was made, and the patient was started on penicillin, 40,000 units every three hours.

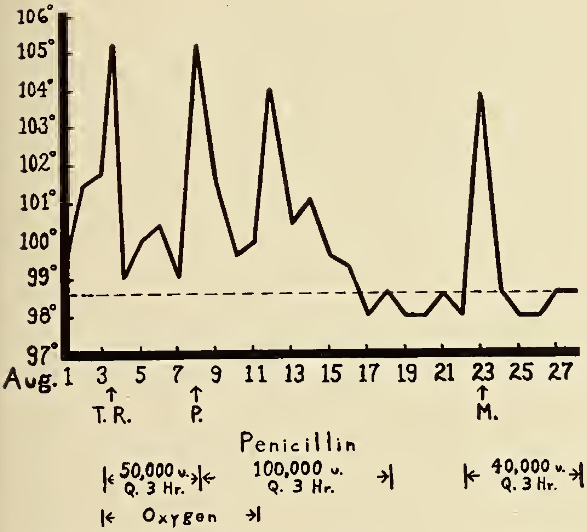

Fig. 1. Temperature chart. T.R. indicates transfusion reaction, P indicates pneumonia, and M, mastitis.

On August 28 the patient was considered fully recovered and was discharged to be followed in the outpatient clinics of Ancker Hospital. Follow-up blood examinations were satisfactory (Table I).

During the twenty-eight days of hospitalization, the patient was given 11,900,000 units of penicillin, fourteen transfusions of whole blood (500 c.c. each), and one transfusion of plasma (500 c.c.), seventeen 5 mg. tablets of folic acid (total amount available), and was in an oxygen tent for eight days (Fig. 1). To obtain the greatest benefit from leukocytes and platelets in the transfused blood, only fresh blood was used, several units being less than two hours old when given. The patient was given parenteral feedings, thiamine chloride 100 mg. daily, ascorbic acid 200 mg. daily, hykinone 1 c.c. (4.8 mg.) daily, and other supportive measures.

Summary and Conclusions

A case of granulocytopenia and thrombocytopenia following sulfadiazine therapy has been reported. To our knowledge this is the fourth case reported of thrombocytopenia due to sulfadiazine. The sensitizing dose was 6 gm. The clinical course was characterized by purpura, hemoptysis, melena, and depression of all the formed blood elements. Following parturition, the patient developed severe uterine hemorrhage, pneumonia and mastitis. The patient survived with massive doses of penicillin, multiple transfusions, oxygen, folic acid and other supportive measures.

Because of the seriousness of the complications, although infrequent, sulfonamide therapy should have careful hematological control.

NAVAL RESERVE

During the months of May and June, a nationwide effort is being made to interest former navy men in joining the naval reserve.

The arguments for the desirability of a large naval reserve, for its effect in preventing future attack by a foreign war-monger and to provide a substantial base upon which to build in case of war, are incontestable.

The educational opportunities which can be utilized by members of the naval reserve cover a wide field. This enables those in a great variety of vocations to better themselves. Periodic two-week training cruises in ships of the reserve fleet afford a desirable way to obtain concentrated instruction. Members of the naval air reserve can retain and improve their flying or mechanical skills at one of the two dozen naval air stations now designated as reserve training centers. These centers, also provide training in radar, sonar, radio, and electronics.

Time spent in the reserve results in a 5 per cent increase in base pay for every three years of membership. Veterans of the army or navy between the ages of seventeen and thirty-nine, as well as non-veterans, are eligible.

VETERINARY MEDICINE

LOUIS A. BUIE, M.D.
Rochester, Minnesota

DISEASE is one of the great tragedies of living things. It is one expression of a struggle which is carried on among different forms of life. Incessantly the conflict goes on without quarter or armistice. Infectious disease is merely a disagreeable instance of a widely prevalent tendency of all living creatures to avoid the necessity of building by their own efforts the materials which they require to survive. Whenever they find it possible to take advantage of the constructive labors of others, they follow that course. Plants, partly nourished by decaying animal remains, synthesize new structures by means of their roots and green leaves. Animals eat the plants, man eats both and bacteria attack all. Without bacteria to maintain the cycles of carbon and nitrogen exchange between plants and animals, all life probably would cease eventually. Plants would have no nitrates and no carbon dioxide with which to maintain their perennial synthesis. Cows and pigs would have no clover, man would have no meat and potatoes, rice and tea, beans and fish or whatever his diet, as governed by geography, may be.

Life is, in a sense, an endless chain of parasitism. That form of parasitism which we call "infection" is as old as animal and vegetable life. Swords and lances, high explosives, and all the modern engines of war have had less effect on the fates of nations than plague, typhus fever, cholera, yellow fever, malaria, typhoid fever, tuberculosis, smallpox, diphtheria and pneumonia. Nations have crumbled under their onslaught.

The partial emergence of mankind from the direful effects of these conditions has been due to the advancement of science. The tremendous technical advances made in the science of medicine have modified greatly the nature of its practice, as well as all of its social and economic relationships. The practice of medicine, once limited almost entirely to the physician, now enjoys the participation of many other professions which are concerned with vital aspects of the medical problem. In many ways the veterinarian must be a scientist far beyond the heights that must be reached by the physician.

Many of the bacterial diseases of animals may cause serious illness in human beings, and animals are susceptible to almost as many diseases as are human beings. Economic problems are not the only factors which demand that diseases of animals be controlled and eradicated whenever possible. There is no doubt that the economic loss to the livestock industry caused by preventable disease has been significant, but this problem cannot be considered to be as vital to man as the effect of those diseases which are communicable to him. Basically, the professional activities of veterinarians and physicians are the same. Both are concerned with the diagnosis and treatment of disease and its control and prevention. Probably the most important functions of your profession are the care of sick and injured animals, the protection of that livestock industry on which the life of our nation greatly depends and the protection of human beings against those diseases which are peculiar to animals but which are communicable to man. Probably in the last instance we shall find the greatest opportunity for co-operation between the veterinary and the medical professions. It would be superfluous for me to discuss before this organization those conditions which are common to animals and which are communicable to man. In fact, it would transcend my capabilities. But I venture to say that many would manifest no little surprise should a complete list of these diseases be recited. One can scarcely believe that glanders, encephalitis, Malta fever, anthrax, tuberculosis, milk sickness, some parasitic diseases, swine erysipelas, psittacosis, cowpox, foot and mouth disease, plague, tularemia, rat-bite fever, infectious jaundice, Rocky Mountain spotted fever and rabies—yes, all of these and probably many other diseases—fall into this category. In humans some diseases, such as rabies, occur very rarely in this age, because of scientific discovery and attainment. But when it strikes, what is more ghastly than rabies? A cursory review of a list such as has been given will dispel at once any thought that the activities of the veterinary physician are chiefly concerned with economic

---

Response of the president of the Minnesota State Medical Association at the fiftieth anniversary banquet of the Minnesota Veterinary Medical Association, Saint Paul, Minnesota, January 7, 1947.

problems. His signal achievement in eradicating tuberculosis of cattle; his accomplishments in dealing with infectious equine encephalomyelitis; the service which he has rendered in practically eliminating glanders as a threat to the health of human beings; the fact that he has prevented undulant fever from becoming a major health problem by his supervision of the milk and meat supply; the fact that his co-operation with the medical profession and the splendid achievement of his specialists in the fields of pathology and bacteriology have made it possible to control many diseases of a parasitic nature; all of these accomplishments and many more reveal the heights which the practice of your profession has attained.

We are living in an age of research. There is no doubt that the progress of our entire civilization is based on the power of the human intellect. When the spark of genius appears in an individual, it should be given the greatest opportunity for development, so that its benefits may be extended. A new opinion may originate with a single individual, but the result which such an opinion may produce will depend on the opportunity which it is given for development and its effect on the minds of those who are ready for its reception.

In veterinary medicine, materials have been collected which present a rich and an imposing appearance, but unless and until these materials can be brought to those who are interested in becoming members of your profession, your greatest ambitions cannot be attained. No doubt many men and women of your profession who are desirous of establishing themselves satisfactorily in their work have been diverted from their purpose by lack of opportunity for educational advancement. It is certain that many have failed to adopt this profession as their life work because of lack of educational facilities. Many have had to be contented with inferior training. Many of these last, nevertheless, have succeeded by dint of ceaseless labor in establishing themselves on a plane above reproach. Never in the history of your organization has there been a greater need or justification for educational expansion.

I know that your present requirements for a degree in veterinary medicine are two years of preveterinary training in a recognized university or college and four years in a veterinary college. I know that since the war there has been a striking increase in the number of both men and women who wish to study veterinary medicine. I know that at Kansas State College one out of every seven individuals who registered wished to study veterinary medicine, but because of lack of facilities in the various colleges, the number of students enrolled in veterinary medicine still shows little increase over that recorded before the war. I know that in 1945 there were ten veterinary colleges in the United States and two in Canada. Also, I know that since then, Illinois Missouri and California have established schools of veterinary medicine, but all this is insufficient. It appears that we may view with optimism the prospect of such an expansion in our own great state university. A similar development is clearly the responsibility of many institutions whose function is the advancement of the teaching of medical science. It ill behooves them to linger in the cloudy obscurity of ancient ideas and practices. Science and industry recognize the important role of highly trained, ethical and independent members of the veterinary profession, and your colleagues in the medical profession are proud of your achievements.

CLINICAL-PATHOLOGICAL CONFERENCE

COR PULMONALE

A. J. HERTZOG, M.D., and A. M. McCARTHY, M.D.
Minneapolis, Minnesota

Dr. A. M. McCarthy: This case (A-46-2348) is that of a twenty-nine-year-old male who had been admitted to the Minneapolis General Hospital on several occasions.

In 1927, at the age of nine years, he had an attack of diphtheria while in Wisconsin, and little is known about the details of the illness. During the attack of diphtheria, he developed gangrene of his right leg. The leg was amputated. A persistent cough followed the illness. In 1928, he was seen elsewhere because of his chronic cough. X-rays at this time showed a parenchymal infiltration and fibrosis in the right upper lung that was thought to be tuberculosis. In 1929 he was treated for tuberculosis elsewhere. Acid-fast bacilli were never demonstrated. Artificial pneumothorax of the right side was maintained for several months and repeated at various times up to 1938.

He was first admitted to the Minneapolis General Hospital in 1938 complaining of a chronic cough. His sputum was negative for acid-fast organisms. Blood pressure was 100/60. Hemoglobin was 85 per cent (Sahli); leukocyte count was 16,500. Serology was negative. Urinalysis showed albumin that varied from a trace to four plus. The clinical impression was pneumonia of the left lower lobe. He responded well to sulfanilamide.

He was next admitted in July, 1940. At this time, he was suffering from a low grade fever and raising approximately 2 ounces daily of thick green purulent sputum. All sputum examinations were negative for acid-fast bacilli. Lipiodal studies showed a saccular type of bronchiectasis of the left lower lobe. Urinalysis showed a trace to four plus albumin with occasional casts and red blood cells. During this admission, he developed a spiking fever of 104° with chills. A friction rub was heard in the left chest. Type 9 pneumococci were found in his sputum. He responded well to sulfanilamide.

He was readmitted in March, 1942, because of chills and fever, weight loss and increased productivity of his cough. Clubbing of the finger tips of both hands was noted. There was dullness over the entire right chest. The left chest was hyperresonant. Crackling erepitant râles could be heard in both lung fields. Heart tones were the loudest to the right of the sternum. His temperature varied from 98° to 102°. Sputums and gastric lavages for tuberculosis on guinea pig inoculations were negative. X-rays showed cystic bronchiectasis with atelectasis of the right lung, and emphysema of the left lung with cystic bronchiectasis of the base of the left lung. The heart and mediastinal structures showed a shifting to the right side of the thorax.

He was readmitted from time to time to the hospital during the next few years complaining of a cough, chills, and fever. Each time he responded well to chemotherapy and expectorants. Each time his urine showed from one to four plus albumin with numerous red blood cells and a few leukocytes per high power field. In June, 1942, his blood pressure was 112/68. A phenolsulphonthalein test showed a total urinary excretion of 49 per cent dye in two hours. A congo red test for amyloidosis showed 62 per cent retention of dye in the blood in one hour. Concentration tests showed a specific gravity of urine that varied from 1.006 to 1.020. Electrocardiograms showed a sinus tachycardia.

His next admission was almost three years later in March, 1945. His temperature varied between 100° and 103°. He expectorated two to three cups of sputum daily. Venous pressure varied from 17 cm. citrate to 21 cm. citrate. Liver dullness was noticed 3 cm. below the right costal margin. A congo red test showed 60 per cent dye retention in one hour. During this hospital stay, he developed dyspnea, ascites, and edema of his ankle. He was digitalized. Plasma proteins were 4.58 gm. of albumin and 1.93 gm. of globulin. Sedimentation rate was 67 mm. in one hour. Sputums were negative for acid-fast bacilli. An electrocardiogram showed right axis deviation.

He was again seen in June, 1945, because of recurrence and increase in dyspnea, ascites and edema of his ankle. Blood pressure was 94/60. He was markedly orthopneic and quite cyanotic. The right border of the heart was 10 cm. to the right of the midline. A loud blowing systolic murmur was heard best on the right side of the chest over the second and third interspaces in the right midclavicular line. His abdomen was distended with fluid present. The liver edge was not palpable. There was a two plus edema of his remaining leg. Venous pressure was 17.5 cm. citrate. Congo red test showed 68 per cent dye retention in one hour. Hemoglobin was 109 per cent (Sahli). He was still expectorating large quantities of sputum. He improved with diuretics, digitalis, and penicillin therapy.

He was readmitted in June, 1946, because of increasing dyspnea, orthopnea, and edema. The liver edge was down to the umbilicus. The neck veins were pulsating. There was questionable liver pulsation.

From the Department of Pathology, Minneapolis General Hospital, A. J. Hertzog, M.D., Pathologist.

Peripheral edema was four plus. Clubbing of the fingers was noted. Venous pressure was 23 cm. of citrate. Circulation time was 18 seconds with calcium gluconate. Blood urea nitrogen was 34 to 44 mg. per cent. Abdominal parententesis removed 1,000 c.c. of fluid. His last admission was in November, 1946. Blood pressure was 140/90. Pulse was 120. He was markedly cyanotic and orthopneic. The findings were similar to the last admission. Two thousand cubic centimeters of fluid were removed from his abdomen. He became cyanotic and expired on November 25, 1946.

Dr. Herman Kosnitscky: This man was living on one lung, as his right lung had been completely collapsed by the inflammatory process and repeated pneumothorax for many years. The left lung was emphysematous. Both lungs with lipiodol studies on x-ray showed a sacular type of bronchiectasis. The question of amyloid disease arose but the laboratory findings by the congo red test were not confirmatory. Towards the latter part of his illness, he began to show signs of congestive right heart failure. This man lived unusually long with right heart failure. Once right heart failure occurs in chronic pulmonary conditions, patients usually die shortly. The earlier diagnosis of tuberculosis of his right lung was never established by finding acid-fast organisms.

Intern: What is the mechanism of right heart failure in this case?

Dr. Hertzog: Pulmonary emphysema is present in practically all of these chronic chest conditions and, by interfering with the capillary circulation of the lungs, becomes the most important factor in the pathogenesis of cor pulmonale. In emphysema increased intra-alveolar pressure can be demonstrated. This increased pressure occurs at the expense of the collapsible capillaries and small blood vessels within the interalveolar septa. The peribronchial fibrosis associated with the bronchiectasis and the atelectatic right lung could be contributing factors.

Student: What was the clinical diagnosis in this case?

Dr. McCarthy: Chronic bronchiectasis with pulmonary emphysema; chronic cor pulmonale with congestive right heart failure; and amyloid disease of the kidneys.

Dr. Hertzog: If there is no further discussion, Dr. McCarthy will give the autopsy findings.

Autopsy

Dr. McCarthy: The body was that of a young white male measuring 166 cm. and estimated to weigh 120 pounds. There was marked cyanosis particularly of the face, fingers, and toes. There was an old amputation of the right leg in the midportion of the thigh. There was grade 4 edema of the entire left lower extremity. The toes and fingers showed marked clubbing. There was present approximately 2,000 c.c. of straw colored fluid within the peritoneal cavity. The liver margin was down 10 cm. below the right costal margin. Both pleural cavities were obliterated by old fibrous adhesions. The right lung was completely collapsed. The left lung was large and voluminous. The pericardial sac contained 800 c.c. of fluid. The heart weighed 490 gm. with practically the entire heart composed of a markedly dilated and hypertrophied right ventricle with a marked dilation of the pulmonary conus.

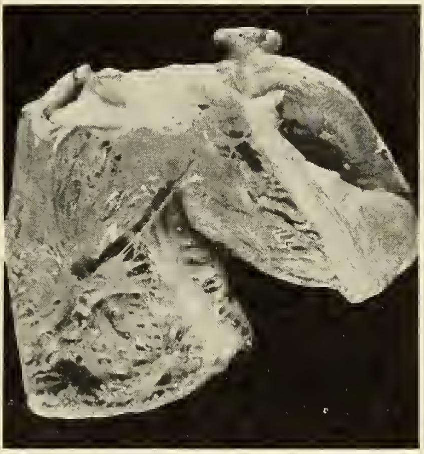

Fig. 1. Heart shows marked hypertrophy and dilatation of right ventricle.

The righ ventricular wall measured 0.7 cm. as compared to the left ventricular wall that measured 1.2 cm. The tricuspid valve showed a marked dilation and measured 14.5 cm. as compared to the mitral valve with a circumference of 10.5 cm. The pulmonary ring measured 8 cm. as compared to the circumference of the aortic valve which measured 7 cm. There was no evidence of any hypertrophy of the left ventricle. The coronary arteries showed a minimum of sclerosis and were patent (Fig. 1).

The right lung weighed 500 gm. and the left lung weighed 1,220 gm. The right lung was completely collapsed and covered with old dense fibrous adhesions. On section of this lung there was complete atelectasis present. Evidence of tuberculosis was not found. The right main pulmonary artery in its lower branch near the bifurcation was partially occluded by an old pale thrombus that was firmly adherent to the wall of the vessel. The larger branches of the pulmonary artery were dilated and contained numerous atheromatous plaques in their walls. The bronchi on the right side were greatly dilated and filled with thick purulent material. This dilation extended out to the periphery of the lung. The left lung was large and voluminous and covered by old adhesions. There were numerous large emphysematous blebs in the upper lobe. On section of the lung there was rather marked hemorrhagic edema present especially in the upper lobe. The main branches of the pulmonary artery were dilated and showed rather marked arteriosclerosis in the form of yellow atheromatous plaques in their walls. The main bronchi of this lung were dilated and filled with purulent mucoid material. This dilation of the bronchi extended out into the smaller bronchi to the periphery of the lung.

The spleen, liver, and kidneys showed gross evidence of passive congestion. The remaining organs showed nothing of note.

Dr. Hertzog: Microscopic examination showed no evidence of amyloid disease of the kidneys, liver, or spleen. Congo red stains were negative. The liver showed long-standing passive congestion. The right lung showed complete atelectasis with no evidence of any tuberculosis. The alveoli of the left lung were dilated with fragmentation of the septa as seen in emphysema. Although intimal atherosclerosis of the larger branches of the pulmonary arteries could be seen, there was a lack of any change within the walls of the smaller pulmonary arteries. This would indicate that most of the resistance responsible for the pulmonary hypertension apparently arose in the small septal vessels. The bronchioles were markedly dilated as seen in bronchiectasis associated with chronic bronchitis.

The anatomical diagnosis was then: (1) cor pulmonale with hypertrophy and dilatation of right ventricle; (2) chronic bronchitis and bronchiectasis; (3) left pulmonary emphysema; (4) right pulmonary atelectasis; (5) thrombosis of right pulmonary artery; (6) atherosclerosis of pulmonary arteries; (7) passive congestion of liver; (8) ascites; (9) left pulmonary edema and bronchopneumonia; and (10) old amputation of right leg.

Discussion

Dr. McCarthy: The term cor pulmonale is commonly used to describe right ventricular cardiac hypertrophy or dilation occurring independently of left ventricular hypertrophy as the result of increased resistance of the blood flow through the pulmonary circulation. Ayerza in 1901 deserves credit for calling our attention to this syndrome. He emphasized the marked cyanosis, calling them "black cardiacs." Ayerza and his pupils stressed syphilis of the pulmonary artery as the etiological factor. Today there is no reason for continuing the use of the term "Ayerza's Disease" other than of historical interest.

Cor pulmonale is commonly classified into acute and chronic types. Acute cor pulmonale is usually caused by massive pulmonary embolism. It is estimated that it is necessary to occlude at least 60 per cent of the total pulmonary vascular bed before heart failure occurs. Hence most nonfatal cases of pulmonary embolism do not cause sufficient obstruction of the pulmonary circulation to cause heart failure. Chronic cor pulmonale is more common and is due to a wider variety of causes. Spain and Handler[9] have recently given us an etiological classification based upon alterations in the thoracic cage, pulmonary vascular system, and pulmonary parenchyma. Clawson[3] in a study of 5,000 hearts in the records of the Pathology Department of the University of Minnesota collected a total of 118 cases of cor pulmonale up to 1946. The etiological factors in order of frequency were pulmonary tuberculosis, forty-five cases; bronchial asthma, twenty-two cases; bronchiectasis, sixteen cases; pulmonary embolism or thrombosis, nine cases; silicosis, seven cases; emphysema, six cases; pulmonary arteriosclerosis, six cases; chest deformity, six cases; pulmonary fibrosis, two cases; and pressure of syphilitic aortic aneurysm on the pulmonary artery, one case. All of these cases had congestive heart failure at the time of death.

George Higgins[6] at Glen Lake Sanatorium worked on the problem of hypertrophy of the right ventricle in pulmonary tuberculosis. He devised a technique where the ventricles were dissected apart and weighed separately. He took into account the general debility of the patient as a result of tuberculosis and with this debility the decrease in the size of the heart. He found a 40 per cent incidence of hypertrophy of the right ventricle associated with pulmonary tuberculosis. He was of the opinion that the pulmonary emphysema associated with the tuberculosis was the principal underlying factor responsible for the increased pulmonary vascular pressure.

In considering pulmonary arteriosclerosis as a cause of cor pulmonale, we are interested primarily in changes in the small arteries and arterioles, as sclerosis confined to the large arteries cannot cause pulmonary hypertension. Immediately one is faced with the problem whether pulmonary arteriosclerosis exists as a primary phenomenon or is secondary to increased pressure within the pulmonary circulation. The same problem exists in systemic hypertension. Brenner in 1935[1] described what he considered to be primary pulmonary arteriosclerosis. Brill and Krygier[2] in 1941 reported one case of their own and analyzed twenty cases from the literature of primary pulmonary vascular sclerosis. They were careful to exclude pulmonary emphysema, left heart failure, mitral lesions or congenital heart lesions which might have thrown strain on the pulmonary circulation. Cross and Kobayashi[4] recently reported a case of primary pulmonary vascular sclerosis in a twenty-month-old infant. Little is known about pulmonary hypertension and its relationship to pulmonary arteriosclerosis, the problem being very similar to that which exists in systemic hypertension. The recent work of catheterization of the right heart and pulmonary artery with direct measurements of the blood pressure within the pulmonary circulation will help throw some light upon the subject of pulmonary hypertension. Westermark has devised a simple technique of recording the pressure within the pulmonary circulation. By means of a manometer, the expiratory pressure necessary to collapse the pulmonary vessels on x-ray is directly proportional to the pressure within the pulmonary circuit, thus affording a means of early diagnosis of an existing pulmonary hypertension.

Deformity of the thorax as a cause of cor pulmonale is relatively rare. Hertzog and Manz[5] in 1945 collected 135 cases from the literature and added one of their own. The mechanism of the increased pulmonary resistance in these cases appears to be largely on the

(Continued on Page 540)

ARTHUS PHENOMENON INDUCED BY THE LOCAL APPLICATION OF PENICILLIN

F. B. MEARS, M.D., and DAVID STATE, M.D.
Minneapolis, Minnesota

ARTHUS, in 1903,[1] noted that if horse serum were injected subcutaneously into rabbits every six days, resorption of serum would take place after the first three of such injections. However, after the fourth injection, infiltration appeared which finally developed into necroses, sequestration and abscess formation. This Arthus described as local anaphalaxis and his observation is universally referred to as the "Arthus phenomenon."

The phenomenon of Arthus has its counterpart in the human being. Such reactions have been reported in the literature since 1909, chiefly in association with the administration of antitoxins. Illustrative cases demonstrate that the Arthus phenomenon results invariably from repeated serum injections, particularly when local serum reactions from a previous inoculation are still present.

Gerlach, in 1923,[1] made a complete microscopic study of the Arthus phenomenon and concluded that the reactions were in no way specific and did not differ from any other inflammatory reaction except in degree. It is believed that the mechanism of the reaction is initiated by an antibody—antigen reaction resulting in arteriolar spasm. The endothelial damage due to the blocking of the vessels by leukocytic and red blood cell thrombi in turn leads to hemorrhage, necroses and slough.

Report of Case

Mrs. S. H. (U.H. No. 769636) was first admitted to the University Hospitals on August 15, 1946, with a history of having noted a painless tumor in the left breast three months prior to admission and a tumor mass in the left axilla three weeks prior to admission. Physical examination revealed an irregular, indurated tumor deep in the inferior portion of the left breast, 10 by 8 by 6 cm. in size and in the anterior part of the left axilla, a hard, matted cluster of nodes, 5 by 3 by 3 cm. Neither tumor was fixed to the skin or underlying structures. The remainder of the physical examination was negative. Blood and urine determinations were within normal limits. X-ray of the chest showed ectasia and calcification of the aorta.

A clinical diagnosis of carcinoma of the breast with axillary metastasis was made and, August 16, 1946, a radical mastectomy was performed under cyclopropane anesthesia. Pathological examination of the 2800 gm. specimen revealed a scirrhous carcinoma of the breast with multiple metastasis to the axillary nodes. Postoperatively the patient received 20,000 units of penicillin sodium intramuscularly every three hours on a prophylactic basis for the duration of her hospital stay; a total of 1,120,000 units were given over a seven-day period. Her course was uneventful and she was discharged from the hospital on August 23, 1946 (Fig. 1).

The wound was dressed on the patient's first clinic visit, August 26, her tenth postoperative day. At this time the skin surrounding the incision in the middle third of the wound over a distance of 6.5 cm. appeared dark; this portion of the wound had been closed under some tension at the time of surgery, though the remaining length of the incision had been approximated with ease. On this date, the patient was started on penicillin in wax and oil, 300,000 units of which were taken in daily intramuscular injections until August 29. At this time, the wound edges of the middle third of the wound were beginning to separate, and it was evident that a slough would occur in this region. The patient was readmitted for debridement and early grafting of the resultant defect.

On admission the involved area of the wound, measuring 5 by 7 cm., was debrided and a wet dressing of 0.5 per cent acetic acid in sterile saline, containing 250 units of penicillin per c.c., applied; in addition the patient was given 50,000 units of penicillin intramuscularly every three hours. The debrided area showed slight infection though the rest of the wound appeared healing and healthy.

On September 3, the patient developed a generalized urticaria, and the edges of the open part of the wound appeared red and angry; there was no associated rise of temperature or pulse. Benadryl, 50 mg. every four hours, was given with some recession of the urticaria; however, the intense wound reaction, in the form of a nonpurulent, necrotizing, intense inflammatory process, spread rapidly to involve three-fourths of the wound. During this period, there was redness and increased heat at the site of the intramuscular injections of the penicillin, though no slough appeared here. On September 5, all penicillin therapy was discontinued and, within the next three days, the inflammatory and necrotizing process in the wound had completely subsided. By September 8, with debridement, the wound presented as a clean, granulating surface.

Comment

Rostenberg and Welch,[2] in studying the types of hypersensitivity induced following the intradermal injections of penicillin in human subjects, noted that in originally nonsensitive individuals who became hypersensitive following repeated injections, the reactions, although eventually developing into a tuberculin type of hypersensitivity, may show transient characteristics simulating the type of reaction seen in the Arthus phenomenon. They postulate that penicillin sodium, injected intradermally, remains in situ for a sufficient time to combine with body proteins, thus forming a heterologous antigen in which the penicillin molecule acts as a hapten. When subcutaneous injections of penicillin were made, no reactions were obtained, and they thought it possible that

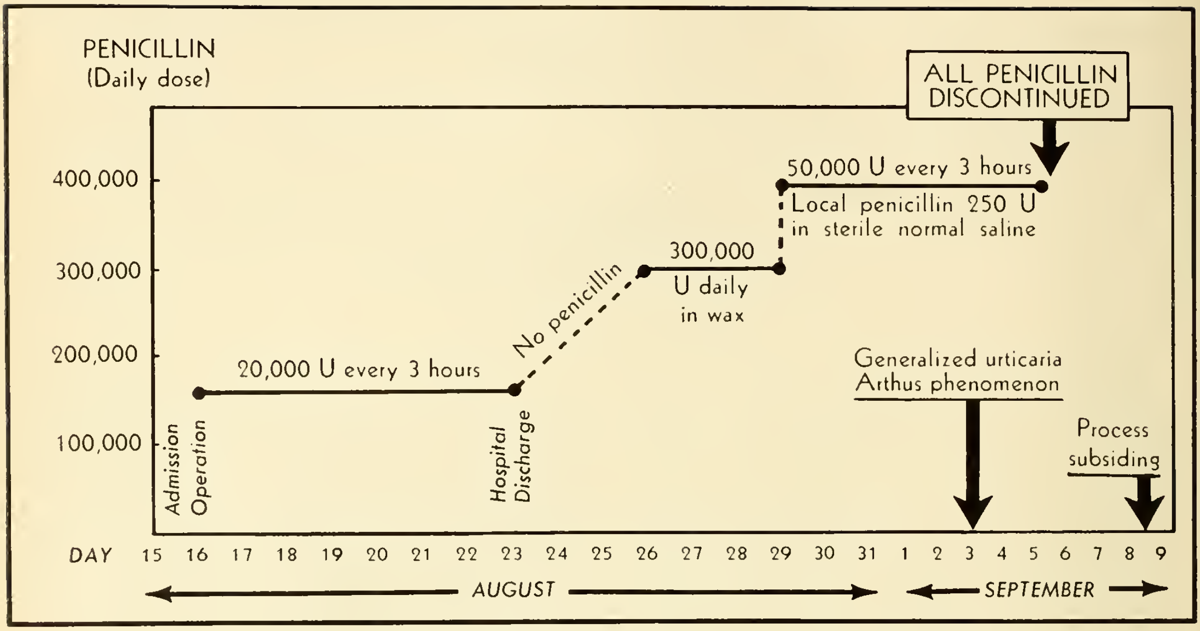

Fig. 1. Record of penicillin therapy in a patient who experienced an Arthus phenomenon.

rapid excretion did not permit sufficient time for the formation of an antigen.

The case presented is believed to represent an Arthus phenomenon induced by the local application of penicillin. It is possible that the penicillin in oil and wax, given five to eight days prior to the reaction was, by virtue of its slow absorption, the factor concerned in the formation of the antigen. It is also conceivable that the antigen was formed by the continued exposure of the wound to the penicillin solution. In either case, the formation of antigen, stimulating the production of antibodies, resulted in a hypersensitive state; the local application of antigen then initiated an antibody-antigen reaction of the type described as local anaphylaxis.

Conclusion

A case is presented in which the local use of a penicillin solution in an open wound in a patient hypersensitive to penicillin resulted in a rapid inflammatory and necrotizing process characteristic of the Arthus phenomenon.

DANGER OF TRANSMITTING MALARIA BY TRANSFUSION

To the Editor:—I believe it would be desirable to renew a warning to medical practitioners that a danger exists in transfusing recipients from donors who have had a past malarial history.

Although I have no extensive data, the transfer of infection has occurred on numerous occasions all over the country. A case reported by Sharnoff, Geiger and Selzer *(Am. J. Clin. Path.* 15:494 [Nov.] 1945) was of particular interest because blood had been stored in a bank for eight days, yet a malarial infection was transferred. When blood is stored at low temperatures, the parasites seem to exist for a long period. The actual limits of time have not been established, but eight days would seem to be quite an interval for an active blood bank.

I have been told of a soldier who had been overseas under suppressive medication and never had had experience with malaria; yet, when his blood was used in this country many months later, a malarial infection occurred in the recipient. Such an occurrence is rather unusual now, although during the war it was seen quite frequently. Most of the men are now out of the malarious areas; hence that danger is minimized. In several thousand cases seen personally no less than a hundred men first had malaria in this country after withdrawal of the suppressive drug used overseas. One man had been off the drug thirteen months before his first attack occurred.

As a routine procedure I believe physicians should be advised never to use blood from any person who has had a past history of malaria. There is an instance in Denver where a Greek's blood was used and malaria resulted although the man had been away from Greece, where he acquired his original infection, for thirty-seven years.

All returning servicemen should be questioned closely about a postmalarial infection. One instance occurred here in which a man was asked specifically whether he had had malaria and he replied in the negative. However, his blood was infectious for the recipient and, on requestioning, he stated that he was afraid that the patient would be denied blood needed very badly and he thought it was of no importance.

It would seem that a safe time limit for a serviceman in this country after withdrawal from the endemic malaria areas and without a past history of malaria would be two years, provided he had not used suppressive drugs in the interim.

NOTES ON THE HISTORY OF MEDICINE IN FILLMORE COUNTY PRIOR TO 1900

By NORA H. GUTHREY
Mayo Clinic
Rochester, Minnesota

(Continued from April issue)

Jacob Wright Magelssen, a son of Hans Gynther Magelssen, who was a Lutheran minister and "provst," and Drude Catherine Haar Daae Magelssen was born on August 11, 1843, at Aafjorden, a town about seventy miles north of Trondhjem, Norway. His parents were worthy representatives of two distinguished families.

The Magelssen family, dating back to 1350, was originally Hanoverian. In 1756 one of the Magelssen men, the grandfather of Jacob Wright Magelssen, immigrated to Norway and there established the family name which is well known and well represented in all the professions. The Daae family were of an illustrious line that traces back to the old nobility of Denmark. Catharine Haar Daae was born at Saltdalen, Norway, in the district where her father was the provost; her brothers, one of whom was Professor Ludvig Kristensen Daae, were brilliant and distinguished historians, economists and scientists. A provst, it may be said, is an official of the church whose responsibilities are comparable to those of a bishop in that he has supervision over other ministers in a large district.

Hans Gynther Magelssen was remarkable for vision, for ardent work on behalf of his church and his people, and for public spirit, especially in laboring for post roads and public schools, and these qualities descended to his children. To Mr. and Mrs. Magelssen were born nine children, six boys and three girls. Johan, the eldest son, was for many years editor of Oslo's famous *Aftenposten.* Kristian, one of the two sons who came to America, was a Lutheran minister at Highland Prairie, Minnesota, near Rushford. Kristen was a noted sculptor. Next came Jacob Wright, the subject of this sketch. Ludvig, the possessor of remarkable dramatic talent and beautiful singing voice, became, not an artist, as he might well have done, but a wholesale importer. Anton, the youngest son, had marked talent as a painter but, believing that one artist in the family was enough, he followed Jacob's example and became a physician. Of the three daughters, Elizabeth, the eldest, a beautiful and talented woman, was married to Peter Voss, head of a distinguished Latin school which bears his name; Valentine, the son of this marriage, became an eminent jurist. The second daughter, Gyda, ahead of her times, was one of the first women in Norway to go into business for herself, establishing a secretarial bureau. The youngest, Sofie, a linguist, newspaper correspondent and writer of books, was married to a Frenchman, P. Groth, and spent most of her adult life in Paris. Her husband and her daughter shared her literary interests and occupations. In 1940, because of the war, Madame Groth came to America, to take up residence in New York. In 1943 she was the only member living of the original family group, unless perhaps Ludvig survived.

When Jacob Wright Magelssen was small, he and the other children had a private tutor because the family lived far from a good school. Before he was four years old he learned to read and write and at the ripe age of eight he was sent with his brothers to a large Latin school for boys at Arendanl. Here he began the study of Latin and German; English was not taught in the school at that time. When, at thirteen, he began the study of English, his textbook was Macauley's *History of England.* After three years at the Latin school, the brothers again had a private tutor for two years. Next, Jacob was sent to Nissen's Latin school for boys, in Oslo, and then to the University of Oslo, from which he was graduated in 1861, at the age of eighteen, with the degree of bachelor of arts. In 1863 he passed the examination for the degree of doctor of philosophy.

Shortly after completion of his university work, Jacob Magelssen came to America, landing in New York during the famous week of July 13 to 16, 1863, when the Draft Riots of the Civil War were in progress in that city. Long afterward, in Rushford, Fillmore County, Minnesota, he learned that his colleague and close friend in the village, Dr. H. C. Grover, who served as an army surgeon in the Civil War, had been in New York City with his regiment, part of the troops that put down the riots. In coming to America Jacob Magelssen had hoped for admission to service in an army hospital in some capacity that would fit him to enter a medical school later, but finding this plan infeasible, he decided to spend the months before college opened in the fall in visiting the new Norwegian settlements in Wisconsin near Koshkonong and Stoughton. It was in this Wisconsin community that he met his future wife, Karen Elizabeth Newberg, who was a native of Norway.

In January, 1886, Dr. Magelssen, aged twenty-two and a half years, was graduated from Rush Medical College in Chicago; he had earned his way through by serving as assistant editor of a Norwegian paper, *Emigranten.* For the next few years after his graduation Dr. Magelssen practiced medicine in Koshkonong; the resident physician of the settlement, Dr. Hanson, wanting to return to Norway, persuaded the young graduate, who was urged by his local friends to accept the place, to take over the practice. For a time subsequently in this general period of his life, Dr. Magelssen was ship's physician on one of the boats of the newly established Norwegian-American line, and during this time his wife (he had been married in 1866 at the age of twenty-three) and children lived in Bergen with Mrs. Magelssen's father. When the shipping company had financial difficulty and the young physician was out of a job, he left his family in Norway and returned to Wisconsin, to the scene of his early medical practice. He was lonely, and impulsively on one fine day of that autumn of 1873 he hitched up his horses and started on the drive of five days to Minnesota to visit his brother, The Reverened Mr. Kristen Magelssen, of Highland Prairie, seven miles from Rushford. Winter set in early that year, Dr. Magelssen contracted inflammatory rheumatism, which affected his heart, and for months at his brother's home he was very ill. It happened that soon after his arrival in Highland Prairie, Dr. Karl O. Bendeke, of Rushford, who was planning to make a trip to Norway, heard of the visiting physician and drove over to ask him to serve in Rushford as locum tenens. By an unforeseen set of circumstances Dr. Bendeke moved permanently to Minneapolis instead of making his visit to Norway, and in the spring of 1874 Dr. Magelssen, pleased with Rushford and the beautiful surrounding country, settled in the village. His wife and children joined him in May. For three years the family lived in rented houses, and then Dr. Magelssen bought the house on the hill which was to be his home for the remainder of his long and useful life.

Under the Medical Practice Act of 1883 Dr. Magelssen received state certificate No. 530 (R). His impress on professional life, as on civic and cultural life in the community and county, was strong. He served his people well and co-operated with the State Board of Health in promoting general welfare. Excerpts from his memoirs concerning the early roads and particularly concerning the epidemic of diphtheria of 1881 and 1882 were quoted in the narrative which preceded the present series of biographical sketches of physicians of Fillmore County.

This man, like his father, was progressive, possessed vision and acumen, and was a tireless worker. Honest and fearless, loyal and dependable, of magnetic personality, a humanitarian and a natural leader, he was a vital factor in accomplishment of measures for the public good. He served a great many terms as mayor of Rushford and, keenly interested in education, was long the president of the school board. The schools of Rushford were among the first in the county to have courses in manual training, home economics and agriculture. Dr. Magelssen was a keen judge of men and, it is said, it was largely through his influence that the local schools were headed by outstanding superintendents, men who justified his opinion of them by going far in their professional field.

Dr. Magelssen's daughters, the Misses Thora and Gyda Magelssen, furnished most of the material on which this sketch is based. In the next few pages appear various verbatim excerpts from their contribution which give vivid highlights on the character and personality of the man:

> He was far ahead of his times in many ways. One of his pet projects was good roads. At every opportunity he preached and pleaded. Much of his argument fell on deaf ears because the people thought that he was considering only his own welfare. Sometimes they would say to him, "We would like you to talk on such an occasion, but don't talk about roads." When he said that every small town was dependent on the farmers 'round about, they laughed at him. . . . Another of his ideas which was ridiculed was that of a community hall.

Dr. Magelssen never lent his time and energies to politics although his abilities and his influence were recognized by many of the political leaders of the state who often tried to enlist him as a party worker. He always refused, saying that he wanted to feel perfectly free to change his opinions and to 'cuss' politicians when they needed it, and also that he could not guarantee not to lose his temper over some clever chicanery. His influence was felt, nevertheless. It was not an uncommon thing to hear a man say, "Well, if a smart man like the doctor is going to vote for so-and-so, that's what I'll do, too." On one occasion, when an important issue was before the town and the citizens were gathered in a mass meeting, discussion was dull and prolix, with much citation of law and precedent. Dr. Magelssen got up, big, forceful and genial: "Fellow citizens, you know what's for the best of this community. Never mind the law. Let's do this thing *right*." And the thing was settled in a few minutes.

In the sense that the term "hobby" means an engrossing and excluding interest in a particular occupation or subject, Dr. Magelssen had no hobbies, for he was interested in everything, although especially in all aspects of nature and particularly in weather, birds, and horses.

> He knew every bird so well that he could recognize many birds by their flight and even by the shadow of their flight cast upon the road ahead of him as he drove. As a part of his daily record he set down the date of arrival of each kind or bird in the spring. He always maintained that birds came north at certain dates, regardless of wind and weather. The robin, for instance, was due between the tenth and the fourteenth of March and arrived even when there was snow on the ground. . . . To the doctor a tree was one of God's most wonderful creations. He would cheerfully have imprisoned anyone who wantonly destroyed one. He often paid out his own hard-earned money to buy a load of wood for a poor man who wanted to chop down a lovely tree for firewood. And Heaven help the chopper who wasn't poor! . . . He was always trying to have a city park board, but there again he was ahead of his time.
>
> In his memoirs more pages are devoted to horses than to anything else. He always owned more than he needed or could really afford. He would drive any kind of a horse, even one so crazy that it took two men to hold it while he climbed into the sulky. He would never knowingly sell one to an unkind master, and many times he bought a horse just to rescue it from a cruel owner. When he was the mayor, it was his rule that no team could be left tied outside more than a short time. After that, the police put the team into a livery stable, and the man had to pay the charges to get it out again. If the man put up a fight, the doctor would call round and settle it in person.
>
> He had a brilliant mind, was an omniverous reader and had a wonderful memory, and all this made him an unusual conversationalist. He liked people and liked to talk with them. It mattered little whether the other fellow was an archbishop or an atheist, a banker or an Indian horse trader, the doctor could always contribute something and make the other do the same. . . . He loved poetry and drama. To read a poem was to remember it for life. . . . His courage was unfailing. Hard work and self-denial, responsibility and worry, sorrow and sacrifice were all in the day's work. . . . His compassion for the poor colored all his life. He could never bring himself to charge what his trips were really worth or to press for payment. "No," he would say, "I can't. There is too much sweat and blood on those dollars." . . . He was generous to a fault. His economies were practiced at his own expense, so that he might give to some one else.
>
> No one is perfect, and the doctor had his faults. He had a hair-trigger temper, and very little patience, except with the sick. When he was really angry, he didn't care what he said or did. With his great size and strength he was not a man to meddle with when he was angry. But he never bore a grudge, and when he offended any one he was quick to make amends. . . .
>
> Nationality and creed meant nothing to him, not just because it is a doctor's business to serve all, but because he respected every man's right to his own faith and remembered the religion of his patients. Often, when he was going to a Catholic home, he would look up the priest and take him along.

In his memoirs, in writing in detail of the researches on leprosy of Armour-Hansen and of Boeck, both of Norway but of different schools of thought as to the origin and method of dissemination of the disease, he stated: "Some years later I had the honor of meeting Dr. Armour-Hansen, whose contention was the opposite of Dr. Boeck's. He presented just as many logical arguments, and plenty of proofs in support of his theory. This has always remained in my mind as an instance of the fact that no man's judgment is infallible and that every proposition is open to argument."

In 1897 the telephone first reached Rushford. The only instrument in town was installed in a small central office and the girl at central sent out a messenger for any one who was called. This limited arrangement led to comic incidents and not infrequently to occurrences of potential tragedy. During a winter storm when the wind was high and the roads drifting full of snow, Dr. Magelssen was obliged to tell one family in which a death was imminent that he probably would not be able to make his usual visit on the following day, but on the pleading of the family he promised to go, making the one condition that if in the meantime the patient, an old man, died, some one was to go to the Hart Exchange and telephone Rushford, to save Dr. Magelssen the trip. On the following day, one of the most terrible in the history of the community, the temperature 50 degrees below zero, the doctor waited until the time that had been specified and then set out. After hours of desperate struggle for himself and his horses he arrived, to find that the old man had died in the previous night and that one of the family duly had telephoned. The message never was delivered; it would be safe to say that the telephone girl did not soon forget Dr. Magelssen's comments when he returned to the village.

His friends were in many places, in all walks of life. Among them were Ibsen, who was also a relative; Bjornson, the novelist, who visited him in Rushford, as Rolvaag also often did; Prestgaard of the *Decorah Posten;* Bishop Lunde, Primate of Norway; Harold Stormoen, the actor; Skovaard, the violinist; Hugh Cooper, the engineer; Governor Nestos; Governor J. A. O. Preus (grandson of the C. K. Preus of Koshkonong); Senators Knut Nelson and Henrik Shipstead.

A friendship which all who knew the men like to remember was that of Dr. Magelssen, Dr. Henry C. Grover, and Dr. H. W. Eldred, the surgeon-dentist, all of Rushford, for each other. Dr. Magelssen was handsome, very tall, large and heavy, but not fat, with unusually broad shoulders and deep chest. He had a broad forehead, a large Roman nose, and heavy dark hair. He always wore a beard. His eyes, intensely blue, held a bright and delighted twinkle, as though the world were a comical and entertaining place, as it was to him. Dr. Eldred was a small wiry man, who also had very bright blue eyes. Dr. Grover was a tall, lean Hoosier, who had a friendly smile and spoke with a slow drawl. Dr. Eldred enjoyed the contrast in size between himself and Dr. Magelssen, who towered above him, and made a point of dancing around the handsome giant, sparring at him in pretended battle.

> When any one of these three men came out on the street, any one passing stopped to talk with him, sure of a lively conversation. When two of them came out at the same time, every one around them stopped to listen. When all three of them came out on the street together, a crowd would gather as promptly as for a circus, for it was certain that there would be a most entertaining scene within a few minutes. They were all very funny men, with keen sense of the comic, quick wits and even quicker tongues, and they kept the crowd roaring with laughter. At public gatherings they could hold up all proceedings if they decided to exchange a little lively repartee.
>
> Dr. Grover had been in Rushford about five years when Dr. Magelssen came, and he was kindness itself to the newcomer. They made many hard, long trips together and helped each other in time of need. They spent long hours together in the office of one or the other, to their mutual profit and pleasure; and if there ever was any discord between them, it was never enough for it to have been mentioned at home. There are many instances cited in his memoirs by Dr. Magelssen and cherished by his children of the strong, sweet, lasting friendship among the three men.

In Rushford, in February, 1881, the death of Mrs. Magelssen occurred. Karen Elizabeth Newberg, mentioned earlier in this account, had been born in Bergen, Norway, on September 24, 1844, and she was married in 1866 to Dr. Magelssen. The seven children of the marriage were: Hans Gynther (1867-1902); Drude Catharine (1869-1871); Karen Henriette (Mrs. S. Rue, 1871——); Mathias Peter (1873-1920); Jacob A. O. (1876——), a rancher in Montana; another Drude Catharine (Mrs. Boyd of Minneapolis); and Kristian (1879——), like Jacob, a rancher in Montana.

Dr. Magelssen was married, a second time, to Thora Larsen, who was born on July 16, 1857, the daughter of Dr. Lauritz Larsen, founder and first president of Luther College, Decorah, Iowa. Mrs. Magelssen died in Rushford on July 3, 1908. To this marriage there were born five children: Karen Elizabeth (Mrs. N. M. Ylvisaker, of Minneapolis); Thora, a schoolteacher, of Rushford; Elsie (Mrs. Einar Jenson, of Newell, Iowa); Gyda, of Rushford; Agnes Margot (Mrs. M. C. Hoppin, in Anchorage, Alaska, in 1941).

Jacob Wright Magelssen died at his home in Rushford on January 9, 1931, from the infirmities of old age, in his eighty-eighth year. He had been a practicing physician, ethical, honored and loved, for sixty-five years, of which fifty-seven years were spent in Rushford, where he settled in 1874. Even after he retired from active practice and had given up his office, Dr. Magelssen continued, until a few months before his death, to see his old patients. Fifty-seven years is a long time, in which a physician may be the friend of many generations; and the knowledge in his community that father or grandfather knew "the doctor" when one or both were young, engenders confidence.

> His magnetism touched every one he met. When he came into a house of illness, so big and full of life, so jolly and yet so wise and capable and sympathetic, the whole atmosphere changed. The doctor radiated . . . the hope and strength and cheer of a vital person who loved life and loved his fellow men. "Why," he would say to some sick child, "when your father was as small as you, and was sick . . ." The little patient would smile and the family would relax.

About **Dr. Masse** of Chatfield, Timothy Halloran, a pioneer settler of the village stated in his *History of Chatfield* (1897) written from memory: "Among the practicing physicians of the early days were Dr. Allen . . . and Dr. Masse, who practiced here for a number of years." Other mention of Dr. Masse has not appeared. Dr. Nelson W. Allen was in Chatfield from 1854 until his death in 1876. It is possible that the name "Masse" was confused with that of Dr. D. N. Morse, in Chatfield as early as 1856, who will be mentioned further.

—Mecklenberg, of Wykoff, mentioned in the official directory of physicians licensed in Minnesota in the period from 1883 to 1890, inclusive, as a holder of an exemption certificate under the "Diploma Law" of 1883, was Dr. Frans Josef (Francis Joseph) Van Mackelenbergh, who came to America from Holland in 1866, to Fillmore County in 1872, and who practiced medicine in Fillmore County successively in Forestville, Spring Valley and Wykoff. His death occurred in Wykoff on March 18, 1892. An account of the life of Dr. Van Mackelenbergh follows in alphabetical place.

Roy A. O. Meidell, a graduate of the University of Christiania, Norway, in 1895, was licensed on January 12, 1897, to practice medicine in Minnesota, and on the following January 27 he filed his state certificate, No. 745, in Fillmore County. Further record in Minnesota has been lacking. On July 3, 1899, R. Meidell, aged thirty years, a graduate of the University of Christiania in 1896 [sic], was licensed to practice in North Dakota. He was a resident of Grank Forks County. In 1907 Dr. R. H. Meidell was in Aneta, Nelson County, North Dakota, the only Meidell in the directory of the American Medical Association. In 1912 Rolf Meidell was in Glendive, Montana, in 1914 in Havre; in 1916 he was in Aneta, North Dakota.

Simeon Paul Meredith was born on January 27, 1852, at Middleton, Wisconsin, the son of a farmer who was a native of Wales. After receiving his early education in the country school near his home, he enrolled as a student at the University of Iowa, in Iowa City, and subsequently for a time he taught the rural school near Middleton. In the next period of his life he qualified as a medical practitioner, and in the middle seventies began his professional career in Jefferson, Wisconsin, and later practiced in Spring Green.

It was probably in 1880 that Dr. Meredith enrolled at the Hahnemann Medical College and Hospital, in Chicago, from which he was graduated in 1882. Shortly after his graduation he came to Minnesota because of ill health, and it has been said that in 1882 he was practicing medicine in Austin, Mower County. In 1887 when, under the Affidavit Law of that year, he received a license to practice in the state, he was living in Plain Prairie. By 1888 he had brought his family to Spring Valley, Fillmore County, and there he remained in successful practice for nearly ten years. (An unverified statement has been noted that in 1897 he was in Owatonna, Steele County.) In February, 1899, he moved from Spring Valley to Pleasant Grove, Olmsted County, where he assumed the practice of the late Dr. Marshall T. Bascomb, who had died on January 28 of that year. A few weeks later, succeeding Dr. Bascomb, he was appointed county physician for the village and township of Pleasant Grove. According to notes from the *Minneapolis Homoeopathic Magazine,* in the spring of 1902 he settled in Grand Meadow, Mower County, near his former location, Spring Valley. By October, 1902, however, he had moved to Windom, Cottonwood County, in the southwestern part of the state, and there he lived for several years before moving to Garden City, southwest of Mankato, in Blue Earth County. From sparse record it would appear that he was in Garden City through 1907 and into 1908; in this period he retired from active medical practice, and in the spring of 1908 established his permanent home in Mankato.

Before leaving Wisconsin, Simeon P. Meredith was married to Fannie E. Glasier, of Bedford, Ohio, the sister of six brothers, most of whom were physicians or dentists. One brother, Gilson Glasier, for more than thirty years, in 1942, had been the librarian of the state law library of Wisconsin. Dr. and Mrs. Meredith were the parents of two children, a daughter and a son. Eva L. Meredith, a graduate of the Windom High School, and a musician, died in 1934. Harlan M. Meredith, who was born on August 22, 1889, at Spring Valley, in 1943 (since 1941) was an employe of the New York Central Railway, in Cleveland, Ohio. In 1942 there were living also Dr. Meredith's brother, George Meredith, in Omaha, and one sister, Mrs. J. F. Fargo, in Los Angeles, California.

Dr. Meredith died in Mankato on September 1, 1930, having suffered many years from bronchitis and asthma. Never in good health, he was not able to enter actively into civic life or to hold public office but applied his limited strength to the practice of his profession. He held respect and liking in the communities of his residence, in all of which he was a home-owning citizen, and left a record of able service to the sick.

Dr. Miller, of Waukokee, Carimona Township, Fillmore County, was mentioned in a county newspaper of January, 1887. The well-known Dr. Luke Miller, of Chatfield and Lanesboro, died in 1881.

(To be continued in June issue)

President's Letter

MEDICAL SERVICE AREA IS KEY TO PHYSICIAN DISTRIBUTION

THOSE of us who were present at the meeting of the officials of the county medical societies of the state on Saturday, March 1, 1947, in Saint Paul, were impressed by a talk which was given by Frank G. Dickinson, Ph.D., director of the Bureau of Medical Economic Research of the American Medical Association. In his discussion he proved that the old method of determining the physician-patient ratio provides an incorrect idea of the efficiency with which physicians are rendering medical service, and he showed further that the key to the question of the availability of medical care and the distribution of physicians may be found in the development of his new concept of medical service areas. Also, he demonstrated in a convincing manner that this method will show, far more accurately than previously used methods, the areas in which physicians practice as well as the availability of medical services.

According to Dr. Dickinson's scheme, the old method of determining the number of people per physician in counties, townships and other political areas is abandoned, and an entirely new concept, based on established marketing principles, is adopted. According to the old concept, it is customary to consider the population in relation to the number of physicians in a political area. One county may have one physician to 1,000 of population, and another county may have one physician to 2,000 of population. Such statistics may be accurate but what significance do they possess? Obviously, very little, because medical care is an economic service which bears no relationship to political boundary lines. Most physicians have patients who come from areas outside the county in which their offices are situated.

Recently, a map of the state of Minnesota has been circulated, in which each county is shaded according to the number of physicians there are per thousand of population. According to this map, white counties have one physician to 1,000 of population or less; black counties have one physician to 3,000 or more persons, and various other shadings are included between the two extremes. With this as an example, Dr. Dickinson brought out the significance of his theory most forcefully. He called attention to the fact that Hennepin and Ramsey counties appeared on the map in white, and Anoka County, which borders these two counties, appeared in black, indicating a ratio of one physician to 3,000 or more people in Anoka County. Obviously, it would be incorrect to assume that people living in Anoka County could not obtain adequate medical care because of the small number of physicians residing in that county. Actually, the people of Anoka County secure much of their medical care in Minneapolis and Saint Paul.

Physicians render service to people who reside in communities which are closely related to the retail trading area, very much as stores draw their customers from small or large areas. A small store may draw customers from an area which covers only a few blocks whereas a large department store may attract customers from a distance of many miles.

The Bureau of Medical Economic Research is attempting to designate medical service areas for the United States. Maps have been sent to all county medical societies. The secretaries of these societies have been asked to indicate on the maps the areas wherein medical care is provided by physicians who reside in primary medical centers within the counties. Not every county includes a primary medical center. A county which is lacking in this respect will be included in one or more of the medical service areas, the primary center or centers of which will lie outside the inadequately supplied county. Much overlapping will come to light. Secretaries in two well-supplied counties, separated by a rural county which does not have a medical center, may each claim that more than half of this rural county is served from a medical center of his county. The secretary of the state medical association will assist the secretaries of the county societies in allocating the disputed territory. At the state level also there will be overlapping, because people who live near the border of a state may look to a large city just across the border for some of their medical service. Elimination of these overlapping interstate areas will require conferences between the state secretaries. Eventually, the border of every medical service area should be drawn so that, in normal times, one or more physicians will reside within the area.

Louis A. Buie

SCHOOLS FOR PRACTICAL NURSES

THE dearth of nurses constitutes a complicated problem. With only 31,000 young women enrolled in nursing training schools in 1946, compared with 39,000 in 1938, and with 33,000 hospital beds unavailable because of the shortage of nurses, the seriousness of the present situation for the public and the hospitals is clearly indicated.[1] Among the reasons for the diminution of enrollment in training schools for nurses, probably the main one, is the opportunity for greater financial compensation in other vocations which do not require such a long period of training, and such a great expense, which recently, it might be noted, has been increasing. The many openings for trained nurses in activities outside the field of private nursing have made the scarcity even more acute.

In recent years the educational requirements for certification as a registered nurse have been on the increase. A few nursing schools, including the University Hospital, have instituted a five-year course. The report of the Committee of the American Surgical Association[2] undoubtedly represents the opinion of the medical profession at large on this trend in the nursing field. It is generally believed that a year of training in nursing will qualify a young woman of average intelligence to render valuable bedside nursing at home or in the hospital. The one-year graduate, of course, cannot take the place of the three-year trained nurse in the care of the seriously ill. The three-year course also is a requisite for further study and training for a Master of Nursing degree, qualifying for teaching and other responsible positions.

Through the co-operation of the nursing and medical professions of Minnesota, a bill providing for the certification of practical nurses after a year of training was recently passed by the state legislature, thus adding Minnesota to the list of twenty other states that have passed such a law.

The next step will be the establishing of training schools for practical nurses. The National League of Nursing Education and the American Nursing Association have declared themselves opposed to the establishment of training schools for practical nurses in conjunction with training schools for registered nurses. The shortage of nursing school instructors may well be one reason for such an attitude. On the other hand, there are a number of nurses' training schools in the state which have been forced to close because they could not meet the requirements established by the national organization of nurses. These schools might well be opened for the training of practical nurses. It should not be unreasonable to expect that the national nurses' organizations will aid rather than obstruct the steps proposed to train practical nurses. While some of the members of the State Board of Examiners of Nurses have shown a spirit of co-operation, others have followed the lead of the national organizations.

The training of practical nurses is of necessity a function of the nursing profession. The medical profession in the past has left the training of nurses to that profession. However, the public, the hospitals and the physicians are vitally concerned and are now entering the picture. To meet the situation a Minnesota Advisory Committee on Nursing has been formed, composed of representatives of the Minnesota State Medical Association, State Hospital Association, State Nursing Association, State Board of Health, State Board of Nursing Examiners, Farm Bureau Federation, State Institutions, State Department of Education, and Catholic Hospitals. This committee has sent out a questionnaire to hospital superintendents to obtain vital information in regard to facilities for training more nurses.

The co-operation of individual physicians, as well as the State Medical Association, in furthering the establishment of training schools for practical nurses, is assured.

TRIMETHADIONE (TRIDIONE) IN PETIT MAL

THE reports of two fatalities resulting from the use of tridione for epilepsy constitute a warning to the profession, since this drug is now available on prescription. The previously reported toxic effects of the drug were few and apparently unimportant. The drug appears highly effective in the prevention of petit mal attacks in childhood, but not of grand mal attacks.

In one of the cases reported,[1] a sixteen-year-old girl had received tridione and dilantin each in doses of 0.1 gm. three times a day for six months. The second case[2] was that of a young woman of twenty-three who had been taking tridione over a period of ten months, usually 4 grains a day. She also had taken phenobarbital for the past nineteen years without ill effect. Both individuals developed severe anemia, granulocytopenia, and purpura, which failed to respond to treatment. At autopsy the bone marrow showed a marked reduction in hemopoietic tissue.

Apparently, tridione must be put in the same category as amidopyrine (to which it is similar in structural formula) in its effect on the bone marrow and on leukocyte production. While idiosyncrasy doubtless explains the effect of both drugs on the bone marrow, and is comparatively rare, yet the patient receiving tridione should have periodic red and white cell counts, and any toxic manifestations such as gastric irritation, nausea, skin eruptions or blurring of vision, should indicate the cessation of its use. It should not be used in the presence of any blood dyscrasia.[3]

DEMEROL

DEMEROL hydrochloride, a synthetic preparation, has been accepted by the Council on Pharmacy and Chemistry, according to the report which appeared in the *Journal of the American Medical Association* of September 21, 1946. The report indicated that the drug has a morphine-like analgesic effect which lies between that of codeine and morphine. While its action is in part due to depression of the parasympathetic endings, it is primarily the result of direct papavarin-like depression of the muscle fibers. Unlike morphine, demerol is not a potent hypnotic.

In an editorial which appeared in our March, 1946, issue, attention was called to the value of demerol in obstetrics. Dispensed in ampoule form with 50 mg. in each c.c., a dose of 100 mg. is given subcutaneously or intramuscularly at the onset of labor, and one or two additional doses are given as required. It is said that demerol does not prolong labor and does not produce a depression of respiration in the infant. Scopolamine is sometimes given with the first dose of demerol because of the former's amnesia effect, but this often makes the patient uncontrollable. The addition of a barbiturate adds a desirable sedative effect.

Demerol may be used to prevent the withdrawal effects in morphine addicts. It should be emphasized, however, that experience has shown that addiction to demerol is not uncommon. In accepting demerol, the Council has required manufacturers to mention the possibility of addiction, and will issue a report in the future on this phase of the use of demerol.

CARE

THERE is something big and fine about this philanthropic organization known as CARE (Cooperative for American Remittances to Europe, Inc.) which is composed of twenty-seven major American welfare agencies, and is operating on a nonprofit government-approved basis. Among the agencies concerned are the American Christian Committee for Refugees, American Friends Service Committee, American Jewish Joint Distribution Committee, Ukranian, Lithuanian, and Yugoslav Relief Committees.

Packages of food, weighing 21 pounds and containing meat, fats, sugar, milk, flour, chocolate, coffee and other essential foods, are already packed and shipped and awaiting orders to be sent to a designated needy person anywhere in Europe except Russia and the Russian zone of Germany (shame on you, Russia). Ten dollars sent to CARE, 50 Broad Street, New York 4, New York, will start a package on its way. Or for the same amount, a Blanket Package containing among other things two army surplus blankets, or a Woolen Package containing woolen cloth, cotton lining, thread, et cetera, can be similarly sent to an address in Europe.

THE STATE MEETING

The ninety-fourth annual meeting of the Minnesota State Medical Association will be held Monday, Tuesday and Wednesday, June 30, July 1 and 2, with headquarters at the Duluth Hotel, Duluth, Minnesota.

This meeting brings together medical men from five states and two provinces of Canada, men in all branches of medicine—general practitioners and specialists.

Duluth, at the head of the Great Lakes, with its refreshing climate, its superb recreational facilities, its central location and its accessibility, is situated in the heart of the Upper Midwest vacation land and is an ideal location for the 1947 convention.

The dates have been selected especially to provide busy Midwest physicians with an inviting opportunity to combine participation in one of the top medical meetings of the year with a vacation over the Fourth of July in Minnesota's scenic Arrowhead Country.

Out-of-State Speakers

Nationally prominent medical men from out-of-state will appear on the program, both for the general meeting and for the special sectional meetings being held by the Minnesota Academy of Ophthalmology and Otolaryngology, the Northwest Pediatric Society, the Minnesota Orthopedic Club, the American College of Chest Physicians, the Minnesota Radiological Society and the Minnesota Society of Clinical Pathologists.

Noted out-of-state speakers include:

Dr. Robert E. Gross, Children's Hospital, Boston, Massachusetts, specialist in heart surgery.

Dr. George E. Shambaugh, Jr., of Chicago, Illinois, Professor of Otolaryngology at Northwestern University.

Dr. M. L. Sussman of New York City, who will deliver the annual Russell D. Carman Lecture in Radiology.

Dr. Benedict Frank Massell of Boston, specialists in rheumatic fever.

Dr. John R. Neefe, a fellow of the National Research Council, Philadelphia. (Dr. Neefe was formerly with the University of Minnesota Medical School.)

Dr. Joseph Molner, Associate Professor of Preventive Medicine and Public Health, Wayne University, Detroit, Michigan, and Medical Consultant for the National Foundation for Infantile Paralysis.

Mrs. Charles W. Sewell, Administrative Director of the Women's Division of the American Farm Bureau Federation, Chicago, Illinois.

Dr. Haven Emerson, School of Public Health, Columbia University, New York.

Drs. Dean Smiley and Fred V. Hein, Consultants in Health and Physical Fitness of the American Medical Association, Chicago, Illinois.

Mr. Tom Collins, Publicity Director, City Mutual Bank and Trust Company, Kansas City, Missouri (Banquet Speaker).

Program Features

A new lectureship has been added this year, with the selection by the Minnesota Society of Clinical Pathologists of Dr. Elexious T. Bell of the Department of Pathology, University of Minnesota, to give the first annual A. H. Sanford Lecture, honoring the work of Dr. Sanford, a pioneer clinical pathologist of this country, who is also a member of the Minnesota State Medical Association.

The A. H. Sanford lectureship was established and dedicated to the Minnesota State Medical Association by the Minnesota Society of Clinical Pathologists. Dr. Bell will speak on the subject, "The Pathology of Diabetes Mellitus."

Another feature will be a booth, where demonstration of interesting gross pathological specimens by the members of the Minnesota Society of Clinical Pathologists will be conducted during morning and afternoon intermissions throughout the three-day session.

This year, as in years past, the last afternoon of the annual meeting will be devoted to a program discussing some important current problem. This meeting is thrown open to the public, and special invitations are sent to representatives of interested groups. This year's question for discussion is the problem of improving health in rural areas, the title chosen for the program being "Rural Health—A Joint Responsibility." In addition to MSMA members, invitations are going to hospital administrators and hospital boards, nurses and representatives of the AFL, CIO, the Farmers Union, the Railroad Brotherhood and the Minnesota Farm Bureau Federation. The program is planned so as to provide an exchange of ideas among farm people, hospital authorities and physicians and a chance for each group to present its views of the various phases of the problem and its proposed solutions.

The Scientific and Non-Scientific Committees of the Association will again hold their annual Committee Breakfasts, preparatory to making their reports to the House of Delegates.

Twenty Roundtable Luncheons—ten on Tuesday and ten on Wednesday, both at 12:15 p.m., will also be held again this year. Recent developments in scientific medicine will be discussed.

The following Special Sectional Meetings are scheduled for this year's program, each of them open to all convention visitors:

Monday, June 30
- 9 a.m.—Minnesota Academy of Ophthalmology and Otolaryngology.

Tuesday, July 1
- 9 a.m.—Minnesota Orthopedic Club.
- 2 p.m.—American College of Chest Physicians.

Wednesday, July 2
- 9 a.m.—A special meeting devoted to investigative work, with speakers presenting latest information on research developments.

Social Events

The Annual Golf Tournament this year will be held at the Northland Country Club on Sunday, June 29, at 1 p.m. Attractive prizes are provided and arrangements are being made by a committee of which Dr. R. L. Nelson, 324 W. Superior St. Duluth, is chairman.

As a special feature, members are invited to participate in a deep-sea fishing excursion along the North Shore of Lake Superior, where catches range up to 55 pounds. No fishing equipment or license is necessary; just appropriate fishing togs. Arrangements are being made through Dr. Karl E. Johnson, 2031 W. Superior Street, Duluth.

"Variety Night" will be held in the Ballroom of the Hotel Duluth at 7:30 p.m. Monday, June 30. Special music and entertainment with refreshments are planned. All convention visitors and wives are invited.

The Annual Banquet, at which the presentation of the Fifty Club certificates and pin and the presentation of the Southern Minnesota Medical Association Medal for the best individual scientific exhibit will be made, is scheduled for 7:00 p.m. Tuesday, July 1. The Presidential Address will be given by Dr. Louis A. Buie of Rochester. Guest speaker is Mr. Tom Collins, Publicity Director, City Mutual Bank and Trust Company, Kansas City, Missouri.

The American College of Chest Physicians will have a luncheon at 12:30 p.m., Tuesday, July 1, in the Tally-ho Room of the Holland Hotel. Reservations are being taken care of by Dr. G. A. Hedberg, Nopeming Sanatorium, Nopeming.

Alumni of Nu Sigma Nu, medical fraternity, will get together Monday evening at 5:30 for a social evening and dinner at the Duluth Athletic Club. This is the first reunion since the meeting before the war.

The Minnesota Academy of Ophthalmology and Otolaryngology is planning a 12:30 p.m. luncheon at The Flame on Monday, June 30. Reservations are being handled by Dr. Archie Olson, 815 Medical Arts Building, Duluth.

A Medical Women's Luncheon will be held at 12:15 p.m. at the Kitchi Gammi Club, reservations being made through Dr. Marie K. Bepko, Cloquet.

All physicians who served in World War II are invited to a luncheon meeting at 12:30 p.m., Monday, June 30, in the Tally-ho Room of the Holland Hotel, sponsored by the Society of Medical Veterans in Duluth. Purpose of the meeting is to give returned medical officers a chance to air their grievances with regard to the manner in which medical departments of the Army and Navy were administered during the war. All former medical officers are invited to come prepared to offer constructive criticism. Reservations are in charge of Dr. Karl E. Johnson, 2031 West Superior Street, Duluth.

A Minnesota Surgical Society luncheon will be held at 12:30 p.m., Tuesday, July 1, at The Flame. Make reservations through Dr. M. G. Gillespie, 205 West Second Street, Duluth.

Exhibits

One of the largest technical exhibits in the history of the Association will be on display in the Duluth Armory. These exhibits will be open for inspection each day beginning at 8 a.m. Arrangements have been made so that both the General Sessions and the Special Sectional Meetings will be recessed both in the morning and in the afternoon for 45-minute periods to permit convention visitors to view the exhibits, demonstrations and the scientific cinema.

There will be a series of five obstetric manikin demonstrations, arranged by the Committee on Maternal Health and sponsored by the Minnesota Department of Health. Three of these will be given in the Duluth Armory. The first at 1 p.m., Monday, June 30, by Dr. Willis E. Brown, Associate Professor of Obstetrics and Gynecology, University of Iowa Medical School, will be repeated at 5 p.m. the same day.

On Tuesday, July 1, Dr. Ralph E. Campbell, Associate Professor of Obstetrics and Gynecology of the University of Wisconsin Medical School, will give two demonstrations, one in the Arrowhead Room of the Hotel Duluth at 12:15 p.m., and the second at the Duluth Armory at 5 p.m.

On Wednesday, July 2, at 12:15 p.m., the final obstetric demonstration will be given by Dr. Mancel T. Mitchell, Clinical Assistant Professor of Obstetrics and Gynecology, University of Minnesota Medical School. This will be held in the Arrowhead Room of Hotel Duluth.

Radiological and Pathological Demonstrations will also be given. Among the scientific exhibitors this year are such organizations as the Minnesota Safety Council, the Minnesota Nurses Association, the Minnesota Public Health Association, the American College of Physicians and Surgeons, the Minnesota Department of Health, the Minnesota Society for the Prevention of Blindness, collaborating with the Department of Ophthalmology of the University of Minnesota, the Division of Vocational Rehabilitation of the State Department of Education, the American Medical Association, the Minnesota State Pharmaceutical Association, and the Minnesota Cancer Society. The Minnesota Society of Clinical Pathologists and the Minnesota Radiological Society are also sponsoring exhibits, as the State Committee on Tuberculosis.

Business Sessions

The usual business sessions will, of course, be held. The Council will have meetings on Saturday, June 28, and all during the convention. The House of Delegates will meet on Sunday, June 29, the day before the convention officially opens, and also on Monday, June 30, the first day of the convention.

Hotel Reservations

It is important that hotel reservations be made at once at the Association office, 496 Lowry Medical Arts Building, Saint Paul 2, Minnesota.

MEDICAL ECONOMICS

George Earl, M.D., Chairman

COUNTY OFFICERS HEAR PROGRESS REPORTS OF MSMA PROGRAMS

(Continued from previous issue)

Viewpoint of Farm Bureau

An able spokesman for the farm people, heard at the County Officers meeting held March 1, was Mr. J. S. Jones of Saint Paul, who is executive secretary of the Minnesota Farm Bureau Federation and one of the members of the Board of Regents of our State University.

His comments generally paralleled those of Dr. Larson, indicating that the medical profession and farm people see eye to eye on their common medical problems, but that in their solution, farm leaders feel there is much to be desired.

Speaking for the 60 thousand farm families who are members of this organization, Mr. Jones reported that prepayment medical service is uppermost in the discussions of rural people these days, and running a close second are demands for adequate hospital facilities and medical and nursing personnel.

Nurse Shortage Plagues Rural Communities

The unfilled gap left in the ranks of registered nurses by recruitment for military service and subsequent attractive opportunities elsewhere were lamented by Dr. W. H. Valentine of Tracy in drawing the attention of the county officers to the present plight of many rural hospitals. To relieve this critical situation, the training of girls for licensure as practical nurses was offered as a partial solution by both Dr. Valentine and Miss Thelma Dodds, R.N., president of the Minnesota Nurses' Association. Both speakers recognized the need for a concerted recruitment drive for all types of candidates for nurses training as the present flow of student nurses into classrooms is not keeping pace with the facilities that are available.

Dr. Valentine charged that the doctors had a bigger stake in a broad state nurse recruitment program than their efforts in that direction to date would indicate.

AMA Officials Describe Changing Medical Order

Leading off the discussion at the evening session, Dr. George F. Lull, secretary and general manager of the American Medical Association, dwelt at some length on the facilities which the AMA stands ready to offer the county medical societies to assist them in working out problems which the changing order in medical practice has produced.

The transition that is taking place, Dr. Lull said, is the result of "extrinsic things that are brought in from the outside, which has led to a changed concept of what medical service implies." As an illustration, he pointed to the United Mine Workers Health and Welfare fund, which could very well set a pattern for other industries.

Closer Liaison with County Medical Societies

An immediate objective of the AMA, Dr. Lull told the county officers, is to establish a closer liaison with the county medical societies to make them more aware of the activities carried on by the parent organization. As a means to that end, the Secretary's Letter was started recently to carry information to the county and state units about its deliberations and undertakings. In this connection, also, he announced that at the time of the centennial observance and annual meeting in Atlantic City in June, the AMA has scheduled a County Officers meeting for Sunday, June 8, to which all county officials who attend the national meeting are invited. It is planned at that meeting to have informal discussions on subjects that seem to be of greatest interest to the people who head up the grass roots of organized medicine.

Noting the importance of prepayment plans in the scheme of things medical, Dr. Lull described the services being offered by the recently created Division of Prepayment Plans within the Council on Medical Service, through which the seal of acceptance of the AMA is given to prepayment plans that qualify by coming up to certain standards. As a related, though independent, organization, he drew attention to Associated Medical Care Plans, Inc., working closely with the Council on Medical Service for the purpose of devising methods to establish some degree of reciprocity among the various prepayment plans in existence.

"It is when doctors step out of their role of scientists to become businessmen that controversy arises," Dr. Lull said. This is particularly true, he reflected, during this formative period when such a variety of prepayment plans are being launched.

The complete answer to the problem of providing prepayment medical service is not yet in sight, Dr. Lull told the doctors. It may well embrace several types of insurance engendering lively competition, which will keep the rates down, and will, in all probability, give the public a better service than if they were operated on a more monopolistic basis.

Public Relations Responsibility of Individual Doctor

The AMA has been accused of failure in its public relations, Dr. Lull said. It was his conviction, however, that the building up or breaking down of public relations for the medical profession is actually almost entirely in the hands of the individual doctor and his personal relationship with his patients—a relationship that determines whether the public is going to think ill or well of the profession as a whole. No amount of newspaper or other publicity, however striking, is likely to alter the judgment of the public, formed on the basis of personal experience with the family doctor, in Dr. Lull's opinion.

As an excellent health education medium, he urged the county societies to avail themselves of the transcribed health platters, which may be borrowed from the AMA headquarters for local station rebroadcasts. Many stations, Dr. Lull said, donate a certain amount of time for public interest programs and would be glad to make use of these transcriptions.

The county officers heard that eleven publications, including the *Journal AMA,* with a weekly circulation of over 130,000 are all a part of the routine of the headquarters staff, along with the keeping of a watchful eye on legislation thrown into both national and state hoppers.

Supply of Medical Service

Speaking as a statistician and economist, Dr. Frank G. Dickinson, director of the American Medical Association's Bureau of Medical Economic Research, presented a different approach in his discussion of the supply of medical service from what is ordinarily heard.

With considerable emphasis, he declared that the supply of medical service cannot be even faintly indicated by the physician-population ratio of a county, although this is the common yardstick used in all current surveys to measure the adequateness of medical service.

"The traditional physician-population ratio by county has no economic meaning whatsoever," he contended. He queried the doctors about the number of patients from towns outside of the county in which their offices are located as proof of his contention that *trading areas*—not county boundary lines—more properly determine the outline of medical service areas.

The second stage of a study of supply, he said, involves a definition of a "unit of supply of medical service." To quote Dr. Dickinson:

> "Every definition I have discussed with my associates has failed to get general approval. Shall one hour of a doctor's time be the unit of supply?
>
> "'No,' my colleagues say, 'it is the amount of work that a doctor can do in one hour which is the unit of supply.'
>
> "Or shall one patient visit be considered a unit of supply? This, too, my colleagues reject because what the doctor does while he is visiting the patient is the real unit of supply."

He concluded, therefore, that until a practical and efficient unit has been agreed upon, one cannot know very much about the functional aspects of supply. One cannot say that a ratio of 800 persons per physician, or 500 persons per physician, or 1,000 persons per physician is adequate unless one can measure in fixed, unchanging units the amount of medical service which one physician can supply, according to Dr. Dickinson. A doctor seeing most of his patients in the hospital, supplies a greater number of units of medical service than a doctor who has to spend one-third or one-half of his time in his automobile en route to visit patients.

Minnesota "Medical Service Area" Map Studied

A map of medical service areas in Minnesota, marked off by county medical society secretaries, co-operating in a joint project sponsored by the State Association and the AMA, furnished an interesting study and was the subject of Dr. Dickinson's concluding remarks.

Typical of chartered maps prepared by other state medical associations, Dr. Dickinson said, was the general overlapping of medical service areas throughout the state as shown on the map, which reflected, also, an overlapping in trade areas.

These areas, he explained, were determined by the relative attractiveness of the retail stores in different towns—upon the transportation facilities available, especially automobile highways, and upon other attractions such as amusement and service facilities represented by doctors, dentists, hospitals, lawyers, repair shops, beauty parlors and various agencies. Obstacles such as toll bridges, poor roads and congested highways reduce the size of trade areas, Dr. Dickinson said.

In like manner, they cut down the medical service areas which normally include one primary trading center, which draws a considerable amount of trade from surrounding territory, and a number of secondary trading centers representing small towns having one or more physicians.

BORDER STATE DOCTORS MUST HEED NARCOTIC REGULATIONS

Because Minnesota is one of the states bordering on Canada, doctors in this state are sometimes caused considerable embarrassment and inconvenience by the enforcement of certain federal narcotic regulations, about which they have not been informed.

The specific law that they unwittingly break is the Narcotic Drugs Import and Export Act which makes it UNLAWFUL FOR A PHYSICIAN TO CARRY NARCOTIC DRUGS IN HIS MEDICAL BAG BACK AND FORTH BETWEEN THE UNITED STATES AND MEXICO AND THE UNITED STATES AND CANADA.

Narcotic drugs found in the possession of a physician when he re-enters the United States are seized and forfeited in compliance with this regulation. This information is being brought to the attention of state physicians in order that they may be correctly informed with reference to this provision of the federal law and saved the unnecessary embarrassment.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

230 Lowry Medical Arts Building, Saint Paul, Minnesota

Julian F. DuBois, M.D., Secretary

David V. Bush, "Health Lecturer," pays $1,000 Fine After Conviction by Jury in Minneapolis

Re State of Minnesota vs. David V. Bush

On April 17, 1947, David V. Bush, sixty-five, Mehoopany, Pennsylvania, was convicted by a jury of seven men and five women in the District Court at Minneapolis, Minnesota, of the crime of practicing healing without a basic science certificate, following a trial lasting eight days. The jury, after listening to the evidence presented by the State of Minnesota, and the testimony offered by Bush and eleven of his followers, needed less than forty-five minutes to find Bush guilty as charged.

Bush, an itinerant health lecturer, who gives his home address as Mehoopany, Pennsylvania, but whose pills, vitamins and other concoctions bear the address of 17234 South Main St., Gardena, California, came to Minneapolis about February 15, and advertised that he would give a health lecture at the Wesley Temple Gymnasium on February 19. The advertisement stated that a collection would be taken up. Knowing in advance Bush's method of doing business, the Minnesota State Board of Medical Examiners immediately ordered an investigation made of his activities. This resulted in a conference with Inspector Eugene Bernath of the Minneapolis Police Department, and police officers were assigned to co-operate with representatives of the Medical Board in following Bush's activities. During Bush's health lecture he announced that he would conduct a so-called health class at the Dyckman Hotel, Minneapolis, commencing the next evening, February 20, and continuing until March 21. Bush also announced that a fee of $3.00 would be charged each person attending the health class. Police officers and a representative of the Medical Board registered for the class. During the next four weeks Bush, under his claim of "free speech," berated the medical profession, law-enforcement officers and others. He would also describe the symptoms of various ailments and would attribute the ailment to the lack or deficiency of the body in certain vitamins and minerals. At the conclusion of this build-up, Bush then offered for sale various pills, powders and other concoctions for which he charged sums ranging from 75 cents to $2. His first lecture was attended by approximately 600 persons and his paid health class was attended by approximately 200 persons, about half of whom purchased some of Bush's preparations each night. When the State of Minnesota was in possession of the facts, the police stepped in and Bush was arrested on March 19, 1947. He fought the case all the way, demanding a preliminary hearing in Municipal Court which was given him, and at the conclusion of which he was held to the District Court for trial by Judge Paul J. Jaroscak under cash bail of $2,000, which was furnished. Bush then demurred to the information and this was overruled by the Hon. John A. Weeks of the District Court of Hennepin County. At the trial, among other things, Bush stated that he had written thirty-two books, had an honorary Ph.D. Degree conferred upon him, and that he was a regularly ordained minister. He also stated that he had been a peanut butter salesman, an actor, and a health lecturer. Following the verdict of guilty in the District Court, the Hon. Levi M. Hall sentenced Bush to pay a fine of $1,000 or to serve nine months in the Minneapolis Workhouse. The Court granted Bush a stay until May 5, 1947, so that he could appeal the case to the Supreme Court of Minnesota if he so desired. However, on April 23, 1947, Bush decided to pay his fine and so far as is known has left the State of Minnesota.

The Minnesota State Board of Medical Examiners desires to express its appreciation for the very fine cooperation received from the Minneapolis Police Department and, particularly, from Inspector Eugene Bernath, police-woman Gladys Cook and the other officers who were assigned to the case. The Medical Board also believes that the splendid results achieved in this case would not have been possible had it not been for the excellent manner in which the trial was conducted for the State of Minnesota by County Attorney Michael J. Dillon, Otto Morck, first assistant county attorney, and Per M. Larson, assistant county attorney.

Saint Paul Painter and Machinist Convicted of Criminal Abortion

Re State of Minnesota vs. Thomas F. Jackamore

On March 27, 1947, Thomas F. Jackamore, fifty-six, 461 Holly Avenue, Saint Paul, Minnesota, was sentenced by the Hon. Royden S. Dane, Judge of the District Court of Ramsey County, to a term of two to eight years at hard labor in the State Prison at Stillwater, following Jackamore's plea of guilty to an information charging him with the crime of abortion. On March 28, 1947, Jackamore was taken before the Hon. Robert V. Rensch, Judge of the District Court of Ramsey County, who had previously, on September 17, 1946, placed Jackamore on probation at the time of his conviction for a similar offense. Judge Rensch made an order on March 31, 1947, revoking the stay of sentence in the previous case and ordered Jackamore to serve two to eight years at hard labor in the State Prison in addition to the sentence imposed by Judge Dane. This means that Jackamore will have to serve four to sixteen years because of his two convictions of the crime of abortion.

In the present case, Jackamore was arrested and charged on March 19, 1947, with the crime of abortion. It was learned that Jackamore had performed ten or twelve criminal abortions during the six months that he was on probation. When arraigned in Court, Jackamore denied his guilt, but subsequently withdrew his plea of not guilty and entered a plea of guilty. Jackamore admitted receiving $150 for each of his criminal abortions which were performed by means of a catheter. Jackamore stated to the Court that he had previously earned his living as a painter and machinist. He has no medical education and holds no license to practice any form of healing in the State of Minnesota. Jackamore was previously convicted in September, 1934, at which time he pleaded guilty to grand larceny in the second degree for participating in the theft of a typewriter from the State of Minnesota. Jackamore served sixty days for that offense.

The Minnesota State Board of Medical Examiners wishes to acknowledge the very fine work done in this case by the Saint Paul Police Department under Chief Charles J. Tierney, and also the splendid work done by Mr. James F. Lynch, County Attorney of Ramsey County. Jackamore has been taken to the State Prison to commence his sentence and it will, undoubtedly, be several years before he is released.

CRUVEILHIER-BAUMGARTEN SYNDROME

(Continued from Page 508)

Other cases will appear, however, which clinically will seem to fall into the group with Cruveilhier-Baumgarten disease, but in which the true anatomic and pathologic condition may not be apparent without necropsy. Unfortunately there is no accurate method of classifying these cases without necropsy.

The case which was just reported falls, I believe, into the group of cases of Cruveilhier-Baumgarten syndrome. This syndrome as was indicated by the review of the literature is characterized by portal hypertension plus evidence of excessive umbilical circulation in the form of an abdominal venous murmur or thrill. In a small group of cases in which this syndrome is present, the necropsy findings may reveal a small liver with little or no fibrosis, a patent umbilical vein and usually splenomegaly. In this small group of cases a distinct etiologic and clinicopathologic disease entity may be present which has been designated Cruveilhier-Baumgarten disease.

Minnesota Academy of Medicine

Meeting of January 8, 1947

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, January 8, 1947. Dinner was served at 7 o'clock and the meeting was called to order at 8:15 by the president, Dr. Ernest M. Hammes.

There were fifty-six members and four guests present.

The first order of business was a discussion of attendance which was discussed by Drs. Lepak and Hall. Dr. Lepak made a motion that the rules in the Constitution be adhered to, and his motion was carried on vote of the membership.

Dean Harold Diehl of the University of Minnesota Medical School was introduced as toastmaster by Dr. Hammes, and made a few well-chosen remarks. Dr. Diehl then introduced Dr. Sweitzer who read his address as retiring president.

PENICILLIN IN THE TREATMENT OF SYPHILIS

S. E. SWEITZER, M.D.
Minneapolis, Minnesota

One of the most interesting subjects in the history of medicine is that of the treatment of syphilis. This has been recently covered in an admirable manner by Moore.[8] He reviewed the chemotherapy of syphilis from 1493 to 1944—a period of 451 years—and divided this into three time periods. The first, lasting 410 years, ran from 1493 to 1903. In this period the treatment of syphilis was entirely empirical and not of much value until about the year 1500 when mercury began to be used and was given in various ways: by mouth, by inhalation, by inunction, and later by injection either intramuscular or intravenous.

The second period ran from 1903 to 1943, or forty years, and saw many changes and much new information about the disease. In 1903, syphilis was for the first time transmitted to experimental animals by Metschnikoff and Roux. In 1905 the treponema pallidum was discovered by Schaudinn, and in 1907 the blood test for syphilis was developed by Wassermann, Neisser and Bruck. These two epoch-making advances were of immense help in the study of the biology of syphilitic infection, and a help in the diagnosis and for determining the effects of treatment.

In 1909 the modern chemotherapy of syphilis began with the discovery of salvarsan "606" by Ehrlich and Hata. This was accomplished after an enormous amount of experimental work by these co-workers. Through the years since 1909 a very good method of treatment was worked out with the use of arsenicals and bismuth, which had taken the place of mercury. This required a continuous treatment of from two to three years, which, besides being an expensive method, left much to be desired from a clinical standpoint, as a treatment of such long duration caused many of the patients to let the treatment lapse before they were cured.

Later an effort was made to give the arsenicals by a continuous drip method over a period of five days. This was later modified by the syringe method. Neosalvarsan was used first and soon replaced by mapharsen. This method was found to be risky, and many deaths occurred from encephalitis, so its use was discarded in many clinics.

The last period in the chemotherapy of syphilis runs from June, 1943, to the present, and marks a real revolutionary change in our concept of what drug or drugs to use and how long to use them. The effort to find a safe and lasting cure is not ended, and changes will and are being made as various methods are tried and evaluated in clinics all over the country.

It all began in June, 1943, when Mahoney, Arnold and Harris[7] demonstrated that penicillin was effective in early syphilis in the rabbit and in man. Because of the importance of the control of the disease, and also of conserving manpower in wartime, an organized investigation of the uses of the drug was begun with the co-operation of the military and governmental agencies and civilian clinics and laboratories.

With the use of penicillin by the army and navy and in many intensive treatment centers, a vast number of cases have been treated by this drug, and many methods have been tried. One of the most important treatment centers was the one set up in Chicago, and much fine work was done there with the very large service that they enjoyed.

The early reports on the results in penicillin-treated cases were glowing and every syphilis clinic in the country started its use as soon as the drug was available. It was found to be a great advance in the therapy of syphilis and to have no mortality attending its use. This happy state of affairs went on until early in 1946 when reports of frequent relapses and slow response to treatment began to appear in the literature, and it became obvious that something had happened to the penicillin.

Because different strains of *Penicillin notatum* and *Penicillin chrysogenum* are used in the manufacture of penicillin, and because different techniques are used in production, five different fractions have been identified. They are F, G, X, K, and dihydro F. Penicillin K is apparently rapidly destroyed or eliminated in the body, and therapeutic levels are not achieved or maintained in the body fluids following ordinary doses.

The early penicillin used was predominately G and was very efficacious. For some months in 1945 all penicillin began to contain increasingly larger amounts of the K factor, and this accounted for the poorer results. The present penicillin is again up to the early qualities and there is an ever-growing possibility that an even better synthetic penicillin will be forthcoming. However, none better than penicillin G is now available.

On February 7 and 8, 1946, there was a meeting of the National Research Council of the United States Public Health Service in Washington, D. C., at which reports were made of studies in forty-three clinics. Some of these papers were later published in the *Journal of the American Medical Association* and give us a summary of what conclusions can be drawn as to the value of penicillin therapy up to that time.

Generally speaking, the earlier in the course of the disease treatment is begun, the better the clinical result. Best results are obtained in the primary sero-negative and early sero-positive cases. Much as with the older form of treatment, there is a distinct drop in the percentage of good results in the cases of secondary syphilis, and more or less indifferent results in late and latent cases of the disease.

It has been found that the administration of mapharsen and penicillin, or penicillin and bismuth, or all three together, give better results than penicillin alone.

The Committee on Medical Research and the United States Public Health Service in a recent report given out show that 6,558 syphilitic patients have been treated with twelve different treatment schedules.[2] The percentage of failure eleven months after treatment was 15 per cent in patients that had received 2,400,000 units of penicillin. By combining 1,200,000 units of penicillin with bismuth, 0.6 to 1 gm., the percentage of failures was cut one-half, as was the case when 300,000 units of penicillin were combined with 320 mg. of mapharsen.

Ingraham and his associates[5] treated forty-nine pregnant women. The women received 2,400,000 units of penicillin only, and of the thirty-seven infants born during the course of this study only one was syphilitic.

Goodwin and Moore[3] treated fifty-seven pregnant women with early syphilis with penicillin. Their recommended dose was 2,400,000. These women gave birth to sixty children, only one of which developed syphilis. Of the remaining fifty-nine, forty-two were followed up long enough to justify a negative diagnosis as regards congenital syphilis. These workers conclude that these results in the prevention of prenatal syphilis are superior to any heretofore attainable with any treatment, and recommend the abandonment of all other methods of treatment.

Platou[11] reported on penicillin in congenital syphilis at the Washington Penicillin Conference in Feruary, 1946. He analyzed the treatment of 191 cases and considered penicillin to be the best agent yet employed in the treatment of congenital syphilis. In his series, serological relapse was 3.6 per cent, and both clinical and serological relapse was 2.6 per cent. The dosage of penicillin for infants should range between a total of 100,000 to 400,000 units per kilogram of body weight. The larger dosage is favored.

Schoch and Alexander[13] in their report on the treatment of early syphilis with penicillin recommended a dosage of at least 2,400,000 units of penicillin and either 40 mg. of mapharsen daily for eight doses, or five injections of bismuth, 0.2 gm. each, on alternate days, or both. For reasons of safety they prefer the bismuth-penicillin combination.

In the reports on the treatment of neurosyphilis with penicillin, Stokes[14] recently came out with a very favorable report. He recommended a dose of at least 4,800,000 units.

O'Leary,[9] on the other hand, was not favorably impressed. He noted some good results in patients with the meningeal forms of the disease but stated that penicillin alone was not capable of controlling the parenchymatous forms of neurosyphilis.

Heller[4] in a recent article reported his conclusions in the evaluation of the treatment of 8,000 cases with various treatment schedules such as the five-day intravenous drip or the syringe method of multiple injections of mapharsen, and the use of penicillin in various doses either alone or with an arsenical or bismuth preparation, or both. He concluded that penicillin with bismuth gave the best results. No deaths were observed when penicillin was used alone. When penicillin was combined with mapharsen and bismuth, there was a mortality of one in 4,312 cases, and with intensive arsenotherapy the mortality ranged from one per 149 cases with the five-day intravenous drip to one in 1,873 cases in those treated by multiple injections.

These mortality figures easily explain why penicillin alone, or with small doses of mapharsen and bismuth, has replaced all previous rapid treatment methods.

Cole[1] recently reported his experience in the treatment of syphilis in pregnancy and recommended a dose of 2,400,000 units or more.

Two of the most recent articles are those of Yampolsky and Heyman[15] and that of O'Leary.[10] Yampolsky and Heyman had good results with penicillin in infantile congenital and acquired syphilis. Their results were poor in interstitial keratitis as well as in juvenile paresis.

O'Leary gave a good review of present-day treatment with penicillin and concluded that it was very good in recent cases and in pregnancy. In latent syphilis it was not so brilliant, and in central nervous system syphilis it gave variable results. O'Leary prefers a schedule of mapharsen, penicillin (2,400,000 units) followed by ten bismuth injections.

The usual method of giving penicillin is an aqueous solution given intramuscularly every three hours for from seven and one-half to ten days. This is done to maintain a constant penicillin level in the blood. Various methods have been tried to give penicillin in a form that would allow slower absorption and less frequent injections. Romansky[12] offered a method using peanut oil and beeswax. He gave a single daily injection of 300,000 units of calcium penicillin in a mixture of peanut oil and beeswax for eight days. These cases were followed from three to six months, and satisfactory results were reported in fifty-eight of the sixty cases.

In a special Venereal Disease Bulletin of the City and County of San Francisco, a report was made of the daily injection of 300,000 units of penicillin in peanut oil and beeswax for a period of ten days. Ninety-eight cases were treated and observed for a period of from three to nine months. The failure rate was 4 per cent. They recommend combining the use of penicillin in oil and wax with the use of the arsenicals and bismuth.

Leifer[6] treated 200 cases of syphilis in various stages with penicillin, 300,000 units in peanut oil and wax daily for eight days. One hundred sixty-five cases were followed. In seventy-three cases of sero-negative primary syphilis he had two clinical relapses, and the final Wassermann tests showed fifty negative, four doubtful and two positive reactions. In sixty-nine cases of sero-positive primary syphilis he had three clinical relapses, and the final Wassermann tests showed thirty-one negative, four doubtful, and eighteen positive. In fifty-eight cases of secondary syphilis he had one clinical relapse, and the final Wassermann tests showed sixteen negative, six doubtful, and twenty-eight positive. He followed them for from two to nine months.

These conflicting reports on the oil and wax method show that this method is still in the experimental stage and is not as yet to be recommended for general use. The combined method of mapharsen, penicillin in oil and wax, and bismuth, may give much better results. This peanut oil and wax method has caused frequent reactions both local and general. Generalized reactions such as urticaria or Herxheimer reactions are not infrequent, while local lesions such as herpes simplex and painful nodules are quite common.

As soon as penicillin became available we began its use in the treatment of syphilis at the Minneapolis General Hospital. We started with a dose of 1,200,000 and soon after increased the dose to 2,400,000. Later, when reports of lessened activity of the penicillin began to come in, we increased the dose to 4,800,000 units. This small series, therefore, is a report of the treatment of syphilis with penicillin alone.

At present we are running another series of cases using mapharsen, penicillin and bismuth. This second series shows promise of giving better results and is the generally accepted method at present. As time goes on, and as reports from the various treatment centers come in, a method will be devised for a safe, rapid and satisfactory treatment of this disease.

Out of a total of 191 cases of syphilis treated with penicillin alone, 119 cases have been observed for at least three months minimum, and for as long as twenty-seven months maximum.

Of these there were twelve sero-negative primary cases. This particular group was observed for from three to sixteen months. Eight cases were followed six months or longer, and all twelve received a dosage of from 1,200,000 units in the first case, 2,400,000 in six cases, up to 5,000,000 in the others. All twelve cases have remained entirely free of any signs or symptoms, and all serologic tests have been negative during the period of observation.

Twenty-two cases of sero-positive primary syphilis were observed at least three months, and eleven cases in this group have been followed twelve months or longer. Fifteen, or 68.2 per cent were negative to all serologic tests at the time of their last examinations. Nine cases of the latter group were females, one of whom delivered a normal child twelve months following her treatment. Seven of the twenty-two cases, including the latter, received 1,200,000 units, seven received 2,400,000 units, and eight received 4,800,000 units total dosage. The six cases (27 per cent) showing strongly positive serologic tests at the time of their last visit were equally distributed between the above total dosages, so there did not seem to be any increased benefits or results derived from increasing the total dosage. One case showed only weakly positive serologic reactions to the more sensitive precipitation tests, and a negative reaction to the Kolmer Wassermann test after four months.

Thirty-one cases with secondary manifestations were followed for periods ranging from four to twenty-nine months. Eleven cases (35.5 per cent) at the time of their last visit still showed strongly positive serologic tests and were considered failures. Two of these were followed for four months, and the other four for sixteen months. Twenty cases (64.5 per cent) reversed to complete negativity and were considered cured.

Nine cases of early latent type of infection were followed for periods ranging from three to eighteen months. Four of these cases (44 per cent) showed negative serologic tests within three months of the time of treatment; five (55 per cent) remained positive and were considered failures.

Thirty-two cases of the late latent type were followed for periods ranging from six months to seventeen months. Only three cases in this group (9 per cent) showed completely negative reactions following treatment and were considered cures. Twenty-nine (91 per cent) remained positive and were considered failures. All of the twenty-nine cases received at least 2,400,000 units, nine cases getting a total of 4,800,000 units.

Twenty-two cases with central nervous system involvement, as evidenced by positive spinal fluid findings, were treated. Nine cases were followed for periods ranging from five to seventeen months. Of these nine cases, two became entirely free of any positive findings. In the other seven there was some decrease in the protein content, and the number of cells found on examination of the spinal fluid. The serologic tests remained positive, however, and in spite of the fact that they showed general improvement physically and an increased feeling of well-being they were considered failures.

There were only two cases of congenital syphilis treated. One infant was first seen at four and one-half months and was given 2,400,000 units of penicillin. This child's blood was completely negative two and one-half months later. The second case, a male infant one year old, was given 1,400,000 units of penicillin and was lost after two months follow-up, at which time the blood serologic tests were still strongly positive.

Two cases of aneurism were treated with penicillin, beginning with 10,000 units every three hours for one day, then 20,000, and slowly up to 50,000 units every three hours. A total of 5,000,000 units was given. One patient did very well and is greatly improved, but the second man died in about three weeks from laryngeal compression after the aneurism increased greatly in size. This unhappy ending should cause us to be very careful in the treatment of cardiovascular syphilis. A preliminary course of bismuth should be given in such cases.

Summary of Cases Treated with Penicillin Alone

In sero-negative primary syphilis all of our cases have remained negative.

In sero-positive primary syphilis only 68.2 per cent became negative, 27 per cent were still positive, and 4.4 per cent were weakly positive.

In secondary syphilis 64.5 per cent became negative and 35.5 per cent were positive.

In early latent syphilis 45 per cent became negative and 55 per cent were positive.

In late latent syphilis only 9 per cent became negative and 91 per cent remained positive.

In a small series of central nervous system syphilis, 22 per cent became negative and the other cases had some changes for the better in the spinal findings and in physical well-being.

Comment

1. Penicillin is a valuable addition to our therapy of syphilis.
2. The earlier it is given the better are the results.
3. A schedule of mapharsen, penicillin and bismuth has replaced all other rapid treatment methods for early syphilis.
4. In the treatment of latent syphilis the same schedule can be used, and it is possible that the results may be as good as the older method of continuous arsenicals and bismuth given over many months.
5. Malaria plus penicillin is the treatment of choice in central nervous system syphilis.
6. In the treatment of cardiovascular or visceral syphilis, a course of bismuth and potassium iodide should precede the administration of penicillin.
7. The results of penicillin therapy in sero-negative primary syphilis and in syphilis in pregnancy are especially brilliant, and these results alone are enough to give penicillin a high place in the treatment of this disease.

Discussion

Dr. P. A. O'Leary, Rochester, Minn.: I enjoyed Doctor Sweitzer's conservatism in regard to penicillin in the treatment of syphilis, because I, too, have that same attitude. During the early period of our experience with penicillin I had the opportunity of observing a large group of patients with acute syphilis at the Chicago Intensive Treatment Center, and it was apparent early in our experience that penicillin, in small doses or in very large doses, would not cure all patients with acute syphilis. It was likewise evident that the earlier treatment was started in the course of the disease, the better were the results; in other words, in the sero-negative chancre phase of syphilis, before the Wassermann had become positive, successful results approximated 95 per cent, whereas in the individual with the late recurrent lesions of the skin and mucous membranes who had had his disease for fifteen or eighteen months, the incidence of failure approximated 40 per cent. When all of the good systems for the treatment of early syphilis are surveyed, it is apparent that the "cure rate" approximates some 80 per cent under all of the various programs. In other words, it would appear that approximately 80 per cent of the patients with early syphilis respond satisfactorily to most any good system of treatment for syphilis, while the remaining 20 per cent are those who have been resistant heretofore to all forms of treatment and are, in all probability, the individuals who eventually develop the late and serious complications of the disease. It has been my experience that many million units of penicillin do not control the disease in individuals who are in this 20 per cent group, so that I felt it necessary to supplement the penicillin with the addition of mapharsen and bismuth. Likewise, it does not seem advisable to regiment the treatment of patients with early syphilis. One should not treat all patients by the same procedure and expect to derive 100 per cent cure any more than one expects that patients with other infectious diseases will all respond to the same doses of any given drug. It has been my practice to give a second and occasionally a third course of mapharsen-penicillin-bismuth when it is evident that the first course is failing to produce satisfactory results.

Our practice is to give four injections of mapharsen on four successive days, 0.05 gm. each, followed by 3,000,000 units of penicillin, in turn followed by fifteen injections of bismuth. If the results are not satisfactory after a period of four to six months, the course is repeated.

One of the many striking values of penicillin has been the reduction in the incidence of asymptomatic neurosyphilis. Under the old chemotherapeutic procedures, approximately 15 per cent of the patients with the early forms of the disease are found to have positive spinal fluid tests. Under the pencillin regime, we are finding that approximately 2 per cent have evidence of activity in the spinal fluid. In a decade or two from now, this finding might well be substantiated by a reduction in the incidence of clinical neurosyphilis. Although the cure rate at the present time is quite comparable to that of the chemotherapeutic procedures, penicillin does offer the opportunity of permitting more patients to complete the course of treatment, so that the future likewise suggests that although the percentage of cure rate is similar to the arsenic-bismuth combinations, the all-over picture will show, however, a higher incidence of cure because more patients will finish the prescribed treatment.

Penicillin in a combination of beeswax and peanut oil permits of giving one injection a day instead of one every three hours, and in a year from now may further simplify the treatment schemes of early syhpilis. The course of treatment of early syphilis with mapharsen-penicillin-bismuth is shorter, is less expensive, offers decidedly fewer complications and gives a satisfactory result in about 60 per cent of the patients. When taken

LUMBAR RETROPERITONEAL GANGLIONEUROMA

Review of Literature and Report of Case in Which the Tumor was Removed Surgically

LAWRENCE M. LARSON, M.D., Ph.D. (Surg.)

Summary*

A case of retroperitoneal ganglioneuroma of the left lumbar sympathetic system is reported in a twenty-eighty-year-old white woman. This tumor had produced definite severe pain locally on the left side and possibly on the right side of the abdomen and lower extremity. Complete relief of these symptoms followed its surgical removal. An interesting postoperative sequela of permanent increase in temperature of the lower extremity on the same side is noted, similar to that occurring with sympathectomy for hypertension.

A review of the literature has been made, and a description of the symptoms, findings and pathologic nature of this tumor are recorded.

Microscopically, these tumors are composed of nerve and connective tissue elements with bundles of nerve fibers in longtitudinal and transverse sections surrounded by a connective tissue stroma. Ganglion cells in various degrees of maturity may be present singly or in groups, and are usually associated with nerve processes. The cytoplasm of these cells is granular, their nuclei may be single or multiple, and the stroma may be of varying degrees of denseness.

Clinically and grossly, these tumors are indistinguishable from neuroma, fibroma, sarcoma, and so forth, and it is only by microscopic examination that the true nature of the tumor can be made out. They are no doubt congenital in origin and probably arise from cell nests displaced in embryonic life. They rarely recur when completely removed and practically never metastasize.

The rarity of this lesion is indicated by the fact that there are probably less than fifty similar cases recorded in the literature and there are no similar tumors recorded in the files of the Department of Pathology, University of Minnesota.

CONGENITAL DIAPHRAGM OF THE DUODENUM

With Case Report and Preoperative X-Ray Studies

WALLACE I. NELSON, M.D., F.A.C.S.

Summary*

Congenital diaphragm of the duodenum is a developmental anomaly in which a membrane, formed by an infolding of the mucosa and submucosa, extends across the lumen of the duodenum. The diaphragm may be complete or it may present an aperture.

A review of the literature reveals thirty-five reported cases of congenital duodenal diaphragm. Of the thirty-five cases reported in the literature, twelve patients were operated upon. *In only six cases of the entire series was the true nature of the lesion discovered during life.*

The author discusses the embryology, and anatomy, including the relationship to the bile and pancreatic ducts and clinical manifestations of this anomaly. The most important factor in the diagnosis is the ability to recognize the presence of the obstruction when it exists. The differential diagnosis between pyloric stenosis and various extrinsic and intrinsic causes of obstruction is discussed.

A case is presented of a twenty-six-year-old woman in whom preoperative x-rays demonstrated such anomaly; this was proved by operation. No other cases have been found in the literature in which the diagnosis was made by x-ray before operation.

Dilatation of the duodenum proximal to the lesion and the presence of a ring of constriction visible at operation at the level of the diphragm are two signs which should lead the surgeon to search for a diaphragm. Mobilization of the duodenum, duodenotomy, and direct removal of the diaphragm are the surgical procedures advocated in preference to short-circuiting operations.

TUBERCULOSIS IN OLDER MEN

So much emphasis has been placed on tuberculosis as a serious disease of girls and young women that its greater havoc among men has not received the attention that it deserves. As a result of the more rapid decline of tuberculosis in females in this country there are today 156 deaths among males to every 100 deaths in females and only at ages ten to thirty is the mortality higher in females. Tuberculosis is increasingly becoming a disease of older, occupied men.—Henry D. Chadwick, M.D., and Alton S. Pope, M.D., The Modern Attack on Tuberculosis, The Commonwealth Fund, Revised, 1946.

(Continued from Page 538)

all together it is economically and therapeutically a great improvement over the older systems of treatment.

DR. GEORGE FAHR, Minneapolis: I shall confine myself to a discussion of the treatment of syphilitic aortitis with penicillin. This discussion will be based upon my observations of the two cases of luetic aortitis treated by Dr. Sweitzer's staff at the Minneapolis General Hospital, as well as on my experience in treating luetic aortitis, including autopsy observations of patients who have died following treatment with salvarsan and neo-salvarsan. My experience in this field goes back to the pre-salvarsan days and for this very reason is of some value, because experience gleaned in treating luetic aortitis and syhilitic gummas in pre-salvarsan days is very helpful in developing a rational therapy with the more effective drugs available since the invention of "606."

The preceding speakers have indicated that penicillin is a very powerful anti-spirocheticidal drug. The use of strong anti-spirocheticidal drugs can lead to the so-called Herxheimer reaction. In luetic aortitis with a moderately large to large aneurysm, the giving of a strong anti-spirocheticidal agent without the necessary preparation may lead to hemorrhage. This has been demonstrated many times in the experience of the past years, especially when salvarsan was given without proper preparation in the early years of salvarsan and neo-salvarsan use in the treatment of luetic aortitis. When there is swelling about the mouths of the coronary arteries in luetic aortitis, the giving of a strong anti-spirocheticidal agent without previous preparation may lead to swelling and edema in this area, leading to partial or almost complete closure of the mouth of the coronary artery with angina pectoris-like pains and frequently sudden death. Where there is aortic insufficiency in luetic aortitis, the exhibition of a strong anti-syphilitic drug may lead to swelling of the commissures of the aortic valves and increased degree of aortic insufficiency and, if left heart failure is already present to some degree, it may lead to an increased degree of left heart failure with congestion and edema of the lungs, and sometimes to heart failure and death.

The first case of luetic aortitis treated by Dr. Sweitzer's assistants was given penicillin without previous preparation. The patient had a large aneurysm of the ascending and innominate arteries. Within ten days after starting the penicillin, at which time 3,400,000 units had been given, the patient developed a marked enlargement of the aneurysm with hemorrhage into the surrounding tissues and was dead within twelve days. The second case of luetic aortitis treated with penicillin developed severe angina pectoris twenty-four hours after being given the first dose of penicillin. This patient luckily did not die but recovered in a few days and is living at the present time.

When one has a patient with luetic aortitis and wishes to treat him with a strong anti-spirocheticidal drug, it is necessary to begin treatment, in my estimation, with the giving of potassium iodide in large doses for about three weeks. Then a course of bismuth injections should be given bi-weekly, extending over a period of six or eight weeks. After this one can begin cautiously with neo-salvarsan, starting in with 0.15 gm. per injection the first week and reaching 0.45 gm. in four weeks. After giving 0.45 gm. for two weeks, the danger of a Herxheimer reaction is over with, and I can see no objection then to giving neo-salvarsan in large doses (at the rate of 0.45 gm. a week). I am inclined to believe that in the future we will use penicillin in the treatment of luetic aortitis with good results and a great deal of gratification to the internist. In my opinion, the internist who is at the same time a competent cardiologist should treat luetic aortitis, because one must not only treat the syphilis but one must also treat the heart.

The meeting adjourned.

A. E. CARDLE, M.D., *Secretary*

CLINICAL-PATHOLOGICAL CONFERENCE

(Continued from Page 516)

basis of pulmonary emphysema although it is possible that mechanical factors associated with the deformity may be contributing factors. In all these cases of kyphoscoliosis, there is usually a rather advanced degree of emphysema.

There is little literature on the subject of cor pulmonale following thoracoplasties for tuberculosis. In the few cases reported, it would again appear that the emphysema of the opposite lung would be the main underlying factor in the development of the cor pulmonale. The fibrosis associated with the tuberculosis would be a contributing one. Dr. Kinsella[7] states that in twenty-five pneumonectomies performed by him, none of these so far shows any signs of right ventricular hypertrophy or dilatation. Two of the twenty-five cases have been followed as long as ten years. Parker[8] in a study of thirty-two cases of essential pulmonary emphysema found enlargement of the right ventricle in 7 per cent of the cases and congestive right heart failure in 44 per cent of the cases. He concluded that the arteriosclerotic changes found in the pulmonary vessels in these cases were secondary to the pulmonary hypertension produced by the emphysema. In pulmonary tuberculosis, silicosis, chronic bronchiectasis, bronchial asthma, and idiopathic pulmonary fibrosis, pulmonary emphysema is almost universally present. When cor pulmonale develops in these cases, it is generally believed that the pulmonary hypertension is the result of the emphysema.

DEARTH OF NURSES

The American Hospital Association has launched an intensified student nurse enrollment program on a nation-wide scale. The campaign will involve the expenditure of thousands of dollars and will utilize newspaper advertisements, magazine articles, the radio, and cards in street cars, buses and office windows. The various national organizations are invited to co-operate.

Minnesota schools of nursing will offer opportunities for the training of a thousand young women, next fall, according to Miss Thelma Dodds, president of the Minnesota Nurses Association.
